1 GENERAL DESCRIPTION

The MS51 is an embedded flash type, 8-bit high performance 1T 8051-based microcontroller. The instruction set is fully compatible with the standard 80C51 and performance enhanced.

The MS51 contains a up to 16K Bytes of main Flash called APROM, in which the contents of User Code resides. The MS51 Flash supports In-Application-Programming (IAP) function, which enables on-chip firmware updates. IAP also makes it possible to configure any block of User Code array to be used as non-volatile data storage, which is written by IAP and read by IAP or MOVC instruction, this function means whole 16K Bytes area all can be use as Data Flash through IAP command. MS51 support an function of configurable Flash from APROM called LDROM, in which the Boot Code normally resides for carrying out In-System-Programming (ISP). The LDROM size is configurable with a maximum of 4K Bytes by CONFIG define. There is an additional include special 128 bytes security protection memory (SPROM) to enhance the security and protection of customer application. To facilitate programming and verification, the Flash allows to be programmed and read electronically by parallel Writer or In-Circuit-Programming (ICP). Once the code is confirmed, user can lock the code for security.

The MS51 provides rich peripherals including 256 Bytes of SRAM, 1K Bytes of auxiliary RAM (XRAM), Up to 18 general purpose I/O, two 16-bit Timers/Counters 0/1, one 16-bit Timer2 with three-channel input capture module, one Watchdog Timer (WDT), one Self Wake-up Timer (WKT), one 16-bit auto-reload Timer3 for general purpose or baud rate generator, two UARTs with frame error detection and automatic address recognition, one SPI, one I^2C , five enhanced PWM output channels, eight-channel shared pin interrupt for all I/O, and one 12-bit ADC. The peripherals are equipped with 18 sources with 4-level-priority interrupts capability.

The MS51 is equipped with three clock sources and supports switching on-the-fly via software. The three clock sources include external clock input, 10 kHz internal oscillator, and one 16 MHz internal precise oscillator that is factory trimmed to $\pm 1\%$ at room temperature. The MS51 provides additional power monitoring detection such as power-on reset and 4-level brown-out detection, which stabilizes the power-on/off sequence for a high reliability system design.

The MS51 microcontroller operation consumes a very low power with two economic power modes to reduce power consumption — Idle and Power-down mode, which are software selectable. Idle mode turns off the CPU clock but allows continuing peripheral operation. Power-down mode stops the whole system clock for minimum power consumption. The system clock of the MS51 can also be slowed down by software clock divider, which allows for a flexibility between execution performance and power consumption.

With high performance CPU core and rich well-designed peripherals, the MS51 benefits to meet a general purpose, home appliances, or motor control system accomplishment.

2 FEATURES

- CPU:
 - Fully static design 8-bit high performance 1T 8051-based CMOS microcontroller.
 - Instruction set fully compatible with MCS-51.
 - 4-priority-level interrupts capability.
 - Dual Data Pointers (DPTRs).
- Operating:
 - Wide supply voltage from 2.4V to 5.5V.
 - Wide operating frequency up to 24 MHz.
 - Industrial temperature grade: -40°C to +105°C.
- Memory:
 - Up to 16K Bytes of APROM for User Code.
 - 4/3/2/1 Kbytes of Flash for loader (LDROM) configure from APROM for In-System-Programmable (ISP)
 - Flash Memory accumulated with pages of 128 Bytes from APROM by In-Application-Programmable (IAP) means whole APROM can be use as Data Flash
 - An additional 128 bytes security protection memory SPROM
 - Code lock for security by CONFIG
 - 256 Bytes on-chip RAM.
 - Additional 1K Bytes on-chip auxiliary RAM (XRAM) accessed by MOVX instruction.
- Clock sources:
 - Default 16 MHz high-speed internal oscillator (HIRC) trimmed to $\pm 1\%$ (accuracy at 25 °C, 5 V), $\pm 2\%$ in all conditions.
 - Selectable 24MHz high-speed internal oscillator (HIRC).
 - 10 kHz low-speed internal oscillator (LIRC) calibrating to $\pm 1\%$ by software from high-speed internal oscillator.
 - On-the-fly clock source switch via software.
 - Programmable system clock divider from 1/2, 1/4, 1/6, 1/8..., up to 1/512.
- Peripherals:
 - Up to 17 GPIO pins and 1 input-only pin. All output pins have individual 2-level slew rate control.
 - Standard interrupt pins $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$.

- Eight channels of pin interrupt, shared for all I/O ports, with variable configuration of edge/level detection.
- Two 16-bit Timers/Counters 0 and 1 compatible with standard 8051.
- One 16-bit Timer 2 with three-channel input capture module and 9 input pin can be selected.
- One 16-bit auto-reload Timer 3, which can be the baud rate clock source of UARTs.
- Three pairs, six channels of pulse width modulator (PWM) output, 10 output pins can be selected., up to 16-bit resolution, with different modes and Fault Brake function for motor control. PWM counter individual interrupt for timer.
- One programmable Watchdog Timer (WDT) with reset options
- One dedicated Self Wake-up Timer (WKT) for self-timed wake-up for power reduced modes.
- Two full-duplex UART ports with frame error detection and automatic address recognition. TXD and RXD pins of UART0 exchangeable via software.
- One SPI port with master and slave modes, up to 8 Mbps when system clock is 16 MHz.
- One I²C bus with master and slave modes, up to 400 kbps data rate.
- One 12-bit ADC, up to 500 ksps converting rate, hardware triggered and conversion result compare facilitating motor control.
- Power management:
 - Two power reduced modes: Idle and Power-down mode.
- Power monitor:
 - Brown-out detection (BOD) with low power mode available, 4-level selection, interrupt or reset options.
 - Power-on reset (POR).
 - Low voltage reset (LVR).
- Strong ESD and EFT immunity.
 - ESD HBM pass 8 kV
 - EFT > ± 4.4 kV
 - Latch-up pass 150 mA
- Development Tools:
 - Nuvoton Nu-Link with KEIL[™] and IAR development environment.
 - Nuvoton In-Circuit-Programmer (Nu-Link).
 - Nuvoton In-System-Programming (ISP) via UART.

Pin Number			Symbol	Multi-Function Description ^[1]
MS51FB9AE	MS51XB9AE	MS51XB9AE		
6	2	3	P1.7/ INT1/ ADC_CH0	P1.7: Port 1 bit 7.
				INT1: External interrupt 1 input.
				ADC_CH0: ADC input channel 0.
4	18	1	P2.0/ nRESET	P2.0: Port 2 bit 0 input pin available when RPD (CONFIG0.2) is programmed as 0.
				nRESET: nRESET pin is a Schmitt trigger input pin for hardware device reset. A low on this pin resets the device. nRESET pin has an internal pull-up resistor allowing power-on reset by simply connecting an external capacitor to GND.
5	17	12	P3.0/ INT0/ OSCIN/ ADC_CH1	P3.0: Port 3 bit 0 available when the internal oscillator is used as the system clock.
				INT0: External interrupt 0 input.
				OSCIN: If the ECLK mode is enabled, Xin is the external clock input pin.
				ADC_CH1: ADC input channel 1.

[1] All I/O pins can be configured as a interrupt pin. This feature is not listed in multi-function description. See Section 17 "PIN INTERRUPT".

[2] UART0_TXD and UART0_RXD pins are software exchangeable by UART0PX (AUXR1.2).

[3] [I2C] alternate function remapping option. I²C pins is software switched by I2CPX (I2CON.0).

[4] [STADC] alternate function remapping option. STADC pin is software switched by STADCPX (ADCCON1.6).

[5] PIOx register decides which pins are PWM or GPIO.

5 BLOCK DIAGRAM

5.1 MS51 16K Series BLOCK DIAGRAM

Figure 5.1-1 shows the MS51 functional block diagram and gives the outline of the device. User can find all the peripheral functions of the device in the diagram.

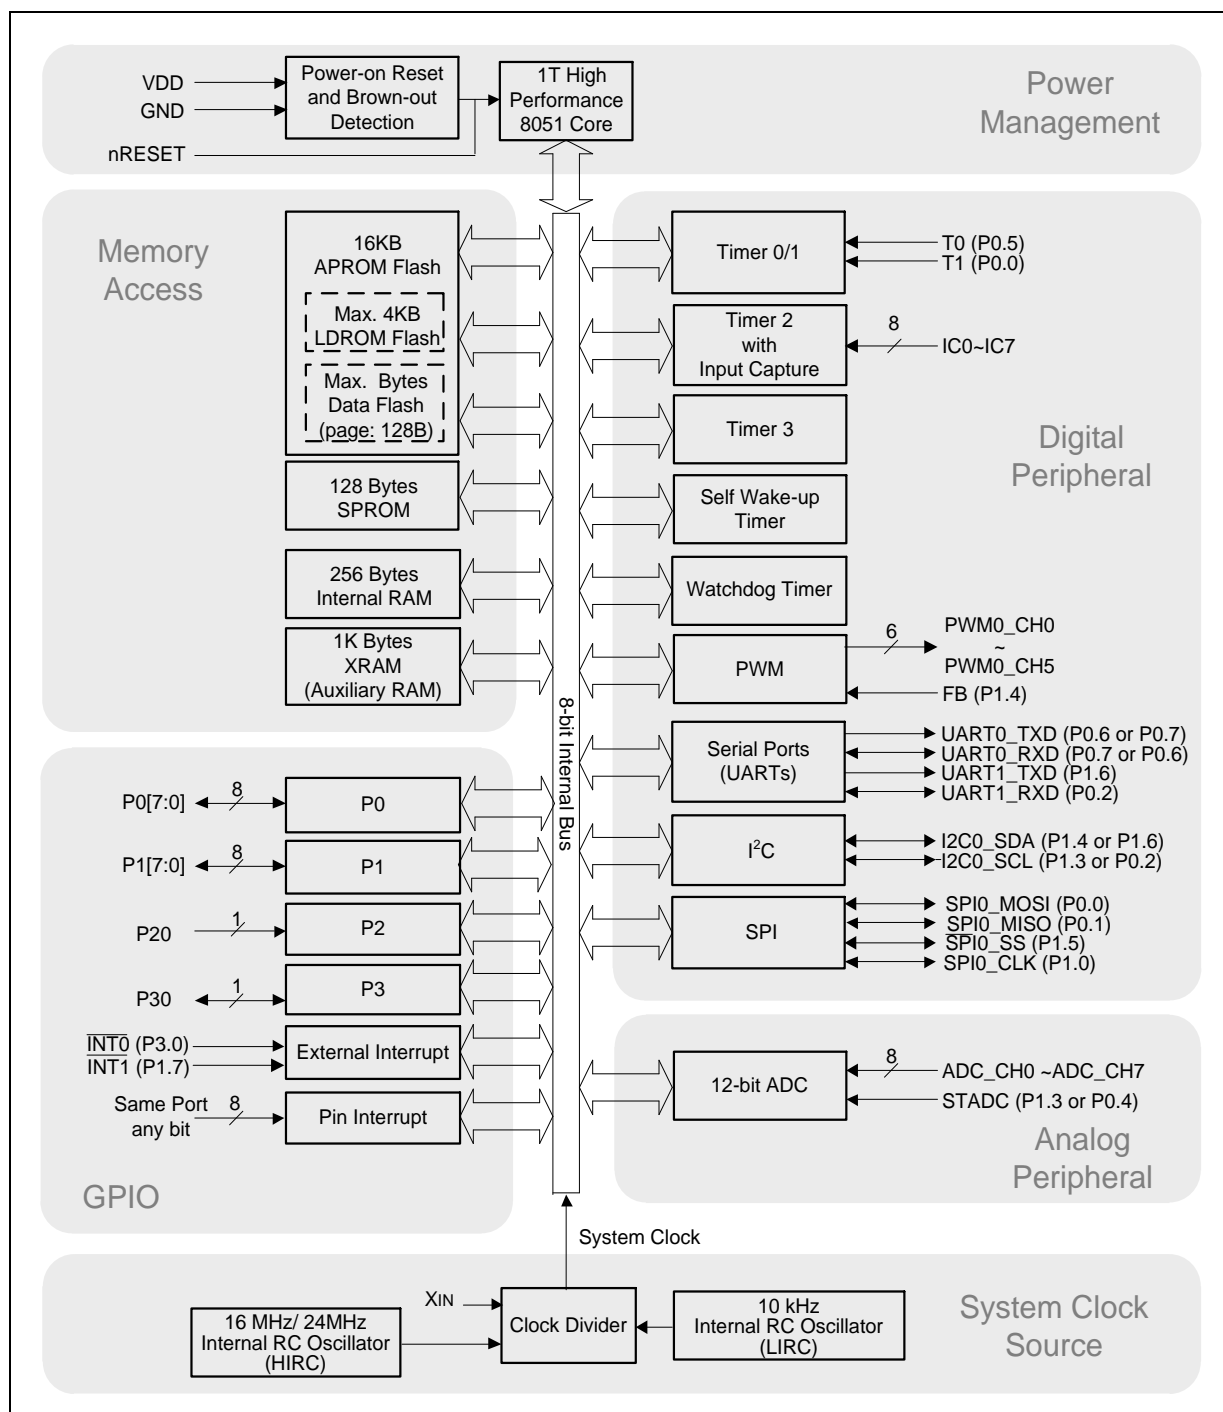

Figure 5.1-1 Functional Block Diagram

6 MEMORY ORGANIZATION

A standard 80C51 based microcontroller divides the memory into two different sections, Program Memory and Data Memory. The Program Memory is used to store the instruction codes, whereas the Data Memory is used to store data or variations during the program execution.

The Data Memory occupies a separate address space from Program Memory. In MS51, there are 256 Bytes of internal scratch-pad RAM. For many applications those need more internal RAM, the MS51 provides another on-chip 1K Bytes of RAM, which is called XRAM, accessed by MOVX instruction.

The whole embedded flash, functioning as Program Memory, is divided into three blocks: Application ROM (APROM) normally for User Code, Loader ROM (LDROM) normally for Boot Code, and CONFIG bytes for hardware initialization. Actually, APROM and LDROM function in the same way but have different size. Each block is accumulated page by page and the page size is 128 Bytes. The flash control unit supports Erase, Program, and Read modes. The external writer tools though specific I/O pins, In-Application-Programming (IAP), or In-System-Programming (ISP) can both perform these modes.

6.1 Program Memory

The Program Memory stores the program codes to execute as shown in Figure 6.1-1 MS51 Program Memory Map. After any reset, the CPU begins execution from location 0000H.

To service the interrupts, the interrupt service locations (called interrupt vectors) should be located in the Program Memory. Each interrupt is assigned with a fixed location in the Program Memory. The interrupt causes the CPU to jump to that location with where it commences execution of the interrupt service routine (ISR). External Interrupt 0, for example, is assigned to location 0003H. If External Interrupt 0 is going to be used, its service routine should begin at location 0003H. If the interrupt is not going to be used, its service location is available as general purpose Program Memory.

The interrupt service locations are spaced at an interval of eight Bytes: 0003H for External Interrupt 0, 000BH for Timer 0, 0013H for External Interrupt 1, 001BH for Timer 1, etc. If an interrupt service routine is short enough (as is often the case in control applications), it can reside entirely within the 8-Byte interval. However longer service routines should use a JMP instruction to skip over subsequent interrupt locations if other interrupts are in use.

The MS51 provides two internal Program Memory blocks APROM and LDROM. Although they both behave the same as the standard 8051 Program Memory, they play different rules according to their ROM size. The APROM on MS51 can be up to 16K Bytes. User Code is normally put inside. CPU fetches instructions here for execution. The MOVC instruction can also read this region.

The other individual Program Memory block is called LDROM. The normal function of LDROM is to store the Boot Code for ISP. It can update APROM space and CONFIG bytes. The code in APROM can also re-program LDROM. For ISP details and configuration bit setting related with APROM and LDROM, see [Section 22.5 “In-System-Programming \(ISP\)” on page 232](#). Note that APROM and LDROM are hardware individual blocks, consequently if CPU re-boots from LDROM, CPU will automatically re-vector Program Counter 0000H to the LDROM start address. Therefore, CPU accounts the LDROM as an independent Program Memory and all interrupt vectors are independent from APROM.

CONFIG1

7	6	5	4	3	2	1	0
-	-	-	-	-	LDSIZE[2:0]		
-	-	-	-	-	R/W		

Factory default value: 1111 1111b

Bit	Name	Description
2:0	LDSIZE[2:0]	LDROM size select This field selects the size of LDROM. 111 = No LDROM. APROM is 16K Bytes. 110 = LDROM is 1K Bytes. APROM is 15K Bytes. 101 = LDROM is 2K Bytes. APROM is 14K Bytes. 100 = LDROM is 3K Bytes. APROM is 13K Bytes. 0xx = LDROM is 4K Bytes. APROM is 12K Bytes.

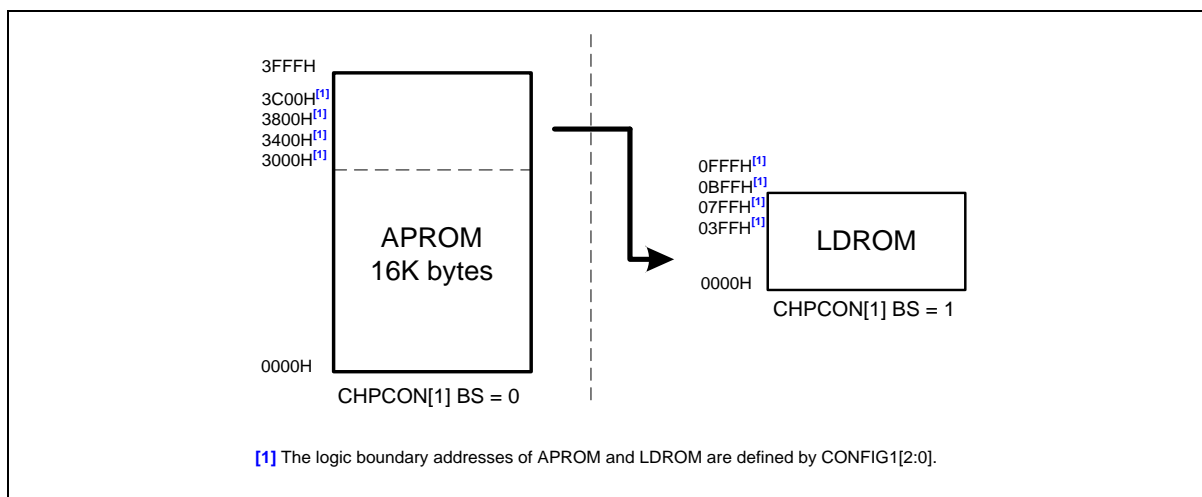

Figure 6.1-1 MS51 Program Memory Map

6.2 Data Memory

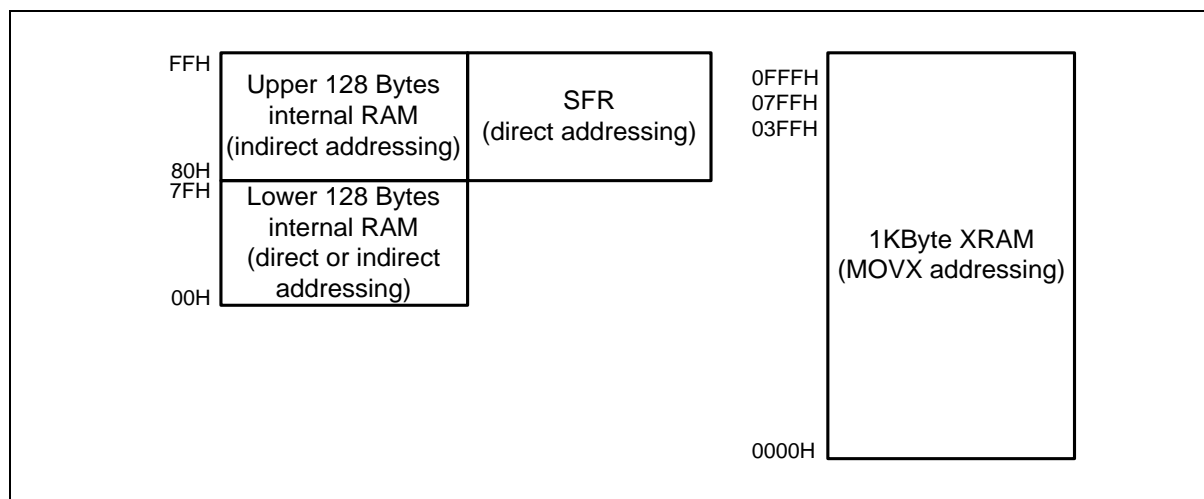

Figure 6.2-1 Data Memory Map

Figure 6.2-1 Data Memory Map 錯誤! 找不到參照來源。 shows the internal Data Memory spaces available on MS51. Internal Data Memory occupies a separate address space from Program Memory. The internal Data Memory can be divided into three blocks. They are the lower 128 bytes of RAM, the upper 128 bytes of RAM, and the 128 bytes of SFR space. Internal Data Memory addresses are always 8-bit wide, which implies an address space of only 256 bytes. Direct addressing higher than 7FH will access the special function registers (SFR) space and indirect addressing higher than 7FH will access the upper 128 bytes of RAM. Although the SFR space and the upper 128 bytes of RAM share the same logic address, 80H through FFH, actually they are physically separate entities. Direct addressing to distinguish with the higher 128 bytes of RAM can only access these SFR. Sixteen addresses in SFR space are either byte-addressable or bit-addressable. The bit-addressable SFR are those whose addresses end in 0H or 8H.

The lower 128 bytes of internal RAM are present in all 80C51 devices. The lowest 32 bytes as general purpose registers are grouped into 4 banks of 8 registers. Program instructions call these registers as R0 to R7. Two bits RS0 and RS1 in the Program Status Word (PSW[3:4]) select which Register Bank is used. It benefits more efficiency of code space, since register instructions are shorter than instructions that use direct addressing. The next 16 bytes above the general purpose registers (byte-address 20H through 2FH) form a block of bit-addressable memory space (bit-address 00H through 7FH). The 80C51 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00H through 7FH.

Either direct or indirect addressing can access the lower 128 bytes space. However, the upper 128 bytes can only be accessed by indirect addressing.

Another application implemented with the whole block of internal 256 bytes RAM is used for the stack. This area is selected by the Stack Pointer (SP), which stores the address of the top of the stack. Whenever a JMP, CALL or interrupt is invoked, the return address is placed on the stack. There is no restriction as to where the stack can begin in the RAM. By default however, the Stack Pointer contains 07H at reset. User can then change this to any value desired. The SP will point to the last used value. Therefore, the SP will be incremented and then address saved onto the stack. Conversely, while popping from the stack the contents will be read first, and then the SP is decreased.

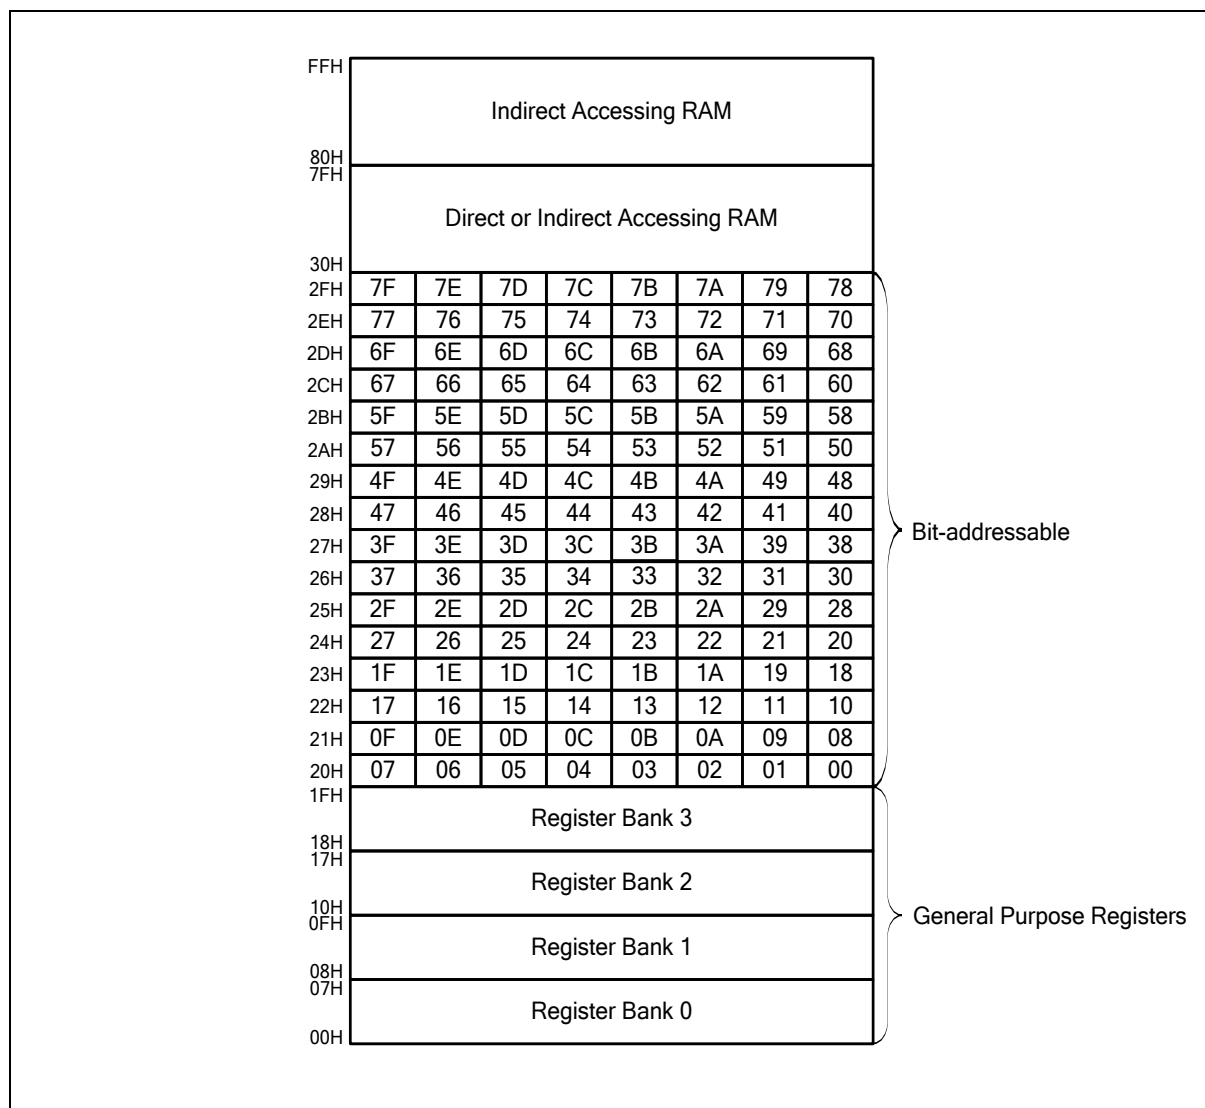

Figure 6.2-2 Internal 256 Bytes RAM Addressing

6.3 On-Chip XRAM

The MS51 provides additional on-chip 1 Kbytes auxiliary RAM called XRAM to enlarge the RAM space. It occupies the address space from 00H through FFH. The 1 Kbytes of XRAM are indirectly accessed by move external instruction MOVX @DPTR or MOVX @Ri. (See the demo code below.) Note that the stack pointer cannot be located in any part of XRAM.

XRAM demo code:

Assembler:

```
MOV    R0, #23H           ;write #5AH to XRAM with address @23H
MOV    A, #5AH
MOVBX  @R0, A
MOV    R1, #23H           ;read from XRAM with address @23H
MOVBX  A, @R1
MOV    DPTR, #0023H       ;write #5BH to XRAM with address @0023H
MOV    A, #5BH
MOVBX  @DPTR, A
MOV    DPTR, #0023H       ;read from XRAM with address @0023H
MOVBX  A, @DPTR
```

C51:

```
unsigned char temp;           //define data variable
unsigned char xdata xtemp _at_ 0x23; //define variable at xdata 0x23;
xtemp = 0x5B;                // write #5BH to XRAM with address @0023H
xtemp++;
temp = xtemp;                //read from XRAM with address @0023H
```

6.4 Data Flash

MS51 Series Data Flash is shared with APROM or LDROM. Any page of APROM or LDROM can be used as non-volatile data flash storage and size no need special configuration. The base address of Data Flash is determined by applying IAP, For IAP details, please see Chapter 22 IN-APPLICATION-PROGRAMMING (IAP). All of embedded flash memory is 128 bytes per page erased.

7 SPECIAL FUNCTION REGISTER (SFR)

The MS51 uses Special Function Registers (SFR) to control and monitor peripherals and their modes. The SFR reside in the register locations 80 to FFH and are accessed by direct addressing only. SFR those end their addresses as 0H or 8H are bit-addressable. It is very useful in cases where user would like to modify a particular bit directly without changing other bits via bit-field instructions. All other SFR are byte-addressable only. The MS51 contains all the SFR presenting in the standard 8051. However some additional SFR are built in. Therefore, some of unused bytes in the original 8051 have been given new functions. The SFR are listed below.

7.1 SFR Page Selection

To accommodate more than 128 SFR in the 0x80 to 0xFF address space, SFR paging has been implemented. By default, all SFR accesses target SFR Page 0. During device initialization, some SFR located on SFR Page 1 may need to be accessed. The register SFRS is used to switch SFR addressing page.

SFRS – SFR Page Selection (TA protected)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	SFRPAGE
-	-	-	-	-	-	-	R/W

Address: 91H

Note: 1. () item means the bit address in bit-addressable SFRs. 2. Reset value symbol description. 0: logic 0; 1: logic 1; U: unchanged; C: see [5]; X: see [3], [6], and [7]. 3. All I/O pins are default input-only mode (floating) after reset. Reading back P2.0 is always 0 if RPD (CONFIG0.2) remains un-programmed 1. After reset OCDDA and OCDCK pin will keep quasi mode with pull high resistor 600 LIRC clock before change to input mode. 4. These SFRs have TA protected writing. 5. These SFRs have bits those are initialized according to CONFIG values after specified resets. 6. BOF reset value depends on different setting of CONFIG2 and V _{DD} voltage level. Please check 7. BOS is a read-only flag decided by V _{DD} level while brown-out detection is enabled.												

Table 7.1-2 SFR Definitions and Reset Values

7.2 ALL SFR DESCRIPTION

Following list all SFR description. For each SFR define also list in function IP chapter.

P0 – Port 0 (Bit-addressable)

7	6	5	4	3	2	1	0
P0.7	P0.6	P0.5	P0.4	P0.3	P0.2	P0.1	P0.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 80H Reset value: 1111 1111b

Bit	Name	Description
7:0	P0[7:0]	Port 0 Port 0 is an maximum 8-bit general purpose I/O port.

SP – Stack Pointer

7	6	5	4	3	2	1	0
SP[7:0]							
R/W							

Address: 81H Reset value: 0000 0111b

Bit	Name	Description
7:0	SP[7:0]	Stack pointer The Stack Pointer stores the scratch-pad RAM address where the stack begins. It is incremented before data is stored during PUSH or CALL instructions. Note that the default value of SP is 07H. This causes the stack to begin at location 08H.

DPL – Data Pointer Low Byte

7	6	5	4	3	2	1	0
DPL[7:0]							
R/W							

Address: 82H Reset value: 0000 0000b

Bit	Name	Description
7:0	DPL[7:0]	Data pointer low byte This is the low byte of 16-bit data pointer. DPL combined with DPH serve as a 16-bit data pointer DPTR to access indirect addressed RAM or Program Memory. DPS (AUXR1.0) bit decides which data pointer, DPTR or DPTR1, is activated.

DPH – Data Pointer High Byte

7	6	5	4	3	2	1	0
DPH[7:0]							
R/W							

Address: 83H Reset value: 0000 0000b

Bit	Name	Description
7:0	DPH[7:0]	Data pointer high byte This is the high byte of 16-bit data pointer. DPH combined with DPL serve as a 16-bit data pointer DPTR to access indirect addressed RAM or Program Memory. DPS (AUXR1.0) bit decides which data pointer, DPTR or DPTR1, is activated.

RWK – Self Wake-up Timer Reload Byte

7	6	5	4	3	2	1	0
RWK[7:0]							
R/W							

Address: 86H Reset value: 0000 0000b

Bit	Name	Description
7:0	RWK[7:0]	WKT reload byte It holds the 8-bit reload value of WKT. Note that RWK should not be FFH if the pre-scale is 1/1 for implement limitation.

PCON – Power Control

7	6	5	4	3	2	1	0
SMOD	SMOD0	-	POF	GF1	GF0	PD	IDL
R/W	R/W	-	R/W	R/W	R/W	R/W	R/W

Address: 87H

Reset value: POR, 0001 0000b Others, 000U 0000b

Bit	Name	Description
7	SMOD	Serial port 0 double baud rate enable Setting this bit doubles the serial port baud rate when UART0 is in Mode 2 or when Timer 1 overflow is used as the baud rate source of UART0 Mode 1 or 3. See Table 14.5-1 Serial Port UART0 Mode / baudrate Description for details.
6	SMOD0	Serial port 0 framing error flag access enable 0 = SCON.7 accesses to SM0 bit. 1 = SCON.7 accesses to FE bit.
4	POF	Power-on reset flag This bit will be set as 1 after a power-on reset. It indicates a cold reset, a power-on reset complete. This bit remains its value after any other resets. This flag is recommended to be cleared via software.
3	GF1	General purpose flag 1 The general purpose flag that can be set or cleared by user via software.
2	GF0	General purpose flag 0 The general purpose flag that can be set or cleared by user via software.

Bit	Name	Description
1	PD	<p>Power-down mode</p> <p>Setting this bit puts CPU into Power-down mode. Under this mode, both CPU and peripheral clocks stop and Program Counter (PC) suspends. It provides the lowest power consumption. After CPU is woken up from Power-down, this bit will be automatically cleared via hardware and the program continue executing the interrupt service routine (ISR) of the very interrupt source that woke the system up before. After return from the ISR, the device continues execution at the instruction, which follows the instruction that put the system into Power-down mode.</p> <p>Note that If IDL bit and PD bit are set simultaneously, CPU will enter Power-down mode. Then it does not go to Idle mode after exiting Power-down.</p>
0	IDL	<p>Idle mode</p> <p>Setting this bit puts CPU into Idle mode. Under this mode, the CPU clock stops and Program Counter (PC) suspends but all peripherals keep activated. After CPU is woken up from Idle, this bit will be automatically cleared via hardware and the program continue executing the ISR of the very interrupt source that woke the system up before. After return from the ISR, the device continues execution at the instruction which follows the instruction that put the system into Idle mode.</p>

TCON – Timer 0 and 1 Control (Bit-addressable)

7	6	5	4	3	2	1	0
TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
R/W	R/W	R/W	R/W	R (level) R/W (edge)	R/W	R (level) R/W (edge)	R/W

Address: 88H Reset value: 0000 0000b

Bit	Name	Description
7	TF1	<p>Timer 1 overflow flag</p> <p>This bit is set when Timer 1 overflows. It is automatically cleared by hardware when the program executes the Timer 1 interrupt service routine. This bit can be set or cleared by software.</p>
6	TR1	<p>Timer 1 run control</p> <p>0 = Timer 1 Disabled. Clearing this bit will halt Timer 1 and the current count will be preserved in TH1 and TL1.</p> <p>1 = Timer 1 Enabled.</p>
5	TF0	<p>Timer 0 overflow flag</p> <p>This bit is set when Timer 0 overflows. It is automatically cleared via hardware when the program executes the Timer 0 interrupt service routine. This bit can be set or cleared by software.</p>
4	TR0	<p>Timer 0 run control</p> <p>0 = Timer 0 Disabled. Clearing this bit will halt Timer 0 and the current count will be preserved in TH0 and TL0.</p> <p>1 = Timer 0 Enabled.</p>
3	IE1	<p>External interrupt 1 edge flag</p> <p>If IT1 = 1 (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine.</p> <p>If IT1 = 0 (low level trigger), this flag follows the inverse of the $\overline{INT1}$ input signal's logic level. Software cannot control it.</p>

Bit	Name	Description
2	IT1	External interrupt 1 type select This bit selects by which type that $\overline{INT1}$ is triggered. 0 = $\overline{INT1}$ is low level triggered. 1 = $\overline{INT1}$ is falling edge triggered.
1	IE0	External interrupt 0 edge flag If $IT0 = 1$ (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine. If $IT0 = 0$ (low level trigger), this flag follows the inverse of the $\overline{INT0}$ input signal's logic level. Software cannot control it.
0	IT0	External interrupt 0 type select This bit selects by which type that $\overline{INT0}$ is triggered. 0 = $\overline{INT0}$ is low level triggered. 1 = $\overline{INT0}$ is falling edge triggered.

TMOD – Timer 0 and 1 Mode

7	6	5	4	3	2	1	0
GATE	C/ \overline{T}	M1	M0	GATE	C/ \overline{T}	M1	M0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 89H Reset value: 0000 0000b

Bit	Name	Description															
7	GATE	Timer 1 gate control 0 = Timer 1 will clock when TR1 is 1 regardless of $\overline{INT1}$ logic level. 1 = Timer 1 will clock only when TR1 is 1 and $\overline{INT1}$ is logic 1.															
6	C/ \overline{T}	Timer 1 Counter/Timer select 0 = Timer 1 is incremented by internal system clock. 1 = Timer 1 is incremented by the falling edge of the external pin T1.															
5	M1	Timer 1 mode select <table><thead><tr><th><u>M1</u></th><th><u>M0</u></th><th><u>Timer 1 Mode</u></th></tr></thead><tbody><tr><td>0</td><td>0</td><td>Mode 0: 13-bit Timer/Counter</td></tr><tr><td>0</td><td>1</td><td>Mode 1: 16-bit Timer/Counter</td></tr><tr><td>1</td><td>0</td><td>Mode 2: 8-bit Timer/Counter with auto-reload from TH1</td></tr><tr><td>1</td><td>1</td><td>Mode 3: Timer 1 halted</td></tr></tbody></table>	<u>M1</u>	<u>M0</u>	<u>Timer 1 Mode</u>	0	0	Mode 0: 13-bit Timer/Counter	0	1	Mode 1: 16-bit Timer/Counter	1	0	Mode 2: 8-bit Timer/Counter with auto-reload from TH1	1	1	Mode 3: Timer 1 halted

0	M0	<table><thead><tr><th><u>M1</u></th><th><u>M0</u></th><th><u>Timer 0 Mode</u></th></tr></thead><tbody><tr><td>0</td><td>0</td><td>Mode 0: 13-bit Timer/Counter</td></tr><tr><td>0</td><td>1</td><td>Mode 1: 16-bit Timer/Counter</td></tr><tr><td>1</td><td>0</td><td>Mode 2: 8-bit Timer/Counter with auto-reload from TH0</td></tr><tr><td>1</td><td>1</td><td>Mode 3: TL0 as a 8-bit Timer/Counter and TH0 as a 8-bit Timer</td></tr></tbody></table>	<u>M1</u>	<u>M0</u>	<u>Timer 0 Mode</u>	0	0	Mode 0: 13-bit Timer/Counter	0	1	Mode 1: 16-bit Timer/Counter	1	0	Mode 2: 8-bit Timer/Counter with auto-reload from TH0	1	1	Mode 3: TL0 as a 8-bit Timer/Counter and TH0 as a 8-bit Timer
<u>M1</u>	<u>M0</u>	<u>Timer 0 Mode</u>															
0	0	Mode 0: 13-bit Timer/Counter															
0	1	Mode 1: 16-bit Timer/Counter															
1	0	Mode 2: 8-bit Timer/Counter with auto-reload from TH0															
1	1	Mode 3: TL0 as a 8-bit Timer/Counter and TH0 as a 8-bit Timer															

TL0 – Timer 0 Low Byte

7	6	5	4	3	2	1	0
TL0[7:0]							
R/W							

Address: 8AH Reset value: 0000 0000b

Bit	Name	Description
7:0	TL0[7:0]	Timer 0 low byte The TL0 register is the low byte of the 16-bit counting register of Timer 0.

TL1 – Timer 1 Low Byte

7	6	5	4	3	2	1	0
TL1[7:0]							
R/W							

Address: 8BH Reset value: 0000 0000b

Bit	Name	Description
7:0	TL1[7:0]	Timer 1 low byte The TL1 register is the low byte of the 16-bit counting register of Timer 1.

TH0 – Timer 0 High Byte

7	6	5	4	3	2	1	0
TH0[7:0]							
R/W							

Address: 8CH Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

7:0	TH0[7:0]	Timer 0 high byte The TH0 register is the high byte of the 16-bit counting register of Timer 0.
-----	----------	--

TH1 – Timer 1 High Byte

7	6	5	4	3	2	1	0
TH1[7:0]							
R/W							

Address: 8DH Reset value: 0000 0000b

Bit	Name	Description
7:0	TH1[7:0]	Timer 1 high byte The TH1 register is the high byte of the 16-bit counting register of Timer 1.

CKCON – Clock Control

7	6	5	4	3	2	1	0
-	PWMCKS	-	T1M	T0M	-	CLOEN	-
-	R/W	-	R/W	R/W	-	R/W	-

Address: 8EH Reset value: 0000 0000b

Bit	Name	Description
6	PWMCKS	PWM clock source select 0 = The clock source of PWM is the system clock F_{SYS} . 1 = The clock source of PWM is the overflow of Timer 1.
4	T1M	Timer 1 clock mode select 0 = The clock source of Timer 1 is the system clock divided by 12. It maintains standard 8051 compatibility. 1 = The clock source of Timer 1 is direct the system clock.
3	T0M	Timer 0 clock mode select 0 = The clock source of Timer 0 is the system clock divided by 12. It maintains standard 8051 compatibility. 1 = The clock source of Timer 0 is direct the system clock.
1	CLOEN	System clock output enable 0 = System clock output Disabled. 1 = System clock output Enabled from CLO pin (P1.1).

WKCON – Self Wake-up Timer Control

7	6	5	4	3	2	1	0
-	-	-	WKTF	WKTR	WKPS[2:0]		
-	-	-	R/W	R/W	R/W		

Address: 8FH Reset value: 0000 0000b

Bit	Name	Description
4	WKTF	WKT overflow flag This bit is set when WKT overflows. If the WKT interrupt and the global interrupt are enabled, setting this bit will make CPU execute WKT interrupt service routine. This bit is not automatically cleared via hardware and should be cleared via software.
3	WKTR	WKT run control 0 = WKT is halted. 1 = WKT starts running. Note that the reload register RWK can only be written when WKT is halted (WKTR bit is 0). If WKT is written while WKTR is 1, result is unpredictable.
2:0	WKPS[2:0]	WKT pre-scalar These bits determine the pre-scale of WKT clock. 000 = 1/1. 001 = 1/4. 010 = 1/16. 011 = 1/64. 100 = 1/256. 101 = 1/512. 110 = 1/1024. 111 = 1/2048.

P1 – Port 1 (Bit-addressable)

7	6	5	4	3	2	1	0
P1.7	P1.6	P1.5	P1.4	P1.3	P1.2	P1.1	P1.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 90H Reset value: 1111 1111b

Bit	Name	Description
7:0	P1[7:0]	Port 1 Port 1 is an maximum 8-bit general purpose I/O port.

SFRS – SFR Page Selection (TA protected)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	SFRPAGE
-	-	-	-	-	-	-	R/W

Address: 91H Reset value: 0000 0000b

Bit	Name	Description
0	SFRPAGE	SFR page select 0 = Instructions access SFR page 0. 1 = Instructions access SFR page 1.

CAPCON0 – Input Capture Control 0

7	6	5	4	3	2	1	0
-	CAPEN2	CAPEN1	CAPEN0	-	CAPF2	CAPF1	CAPF0
-	R/W	R/W	R/W	-	R/W	R/W	R/W

Address: 92H Reset value: 0000 0000b

Bit	Name	Description
6	CAPEN2	Input capture 2 enable 0 = Input capture channel 2 Disabled. 1 = Input capture channel 2 Enabled.
5	CAPEN1	Input capture 1 enable 0 = Input capture channel 1 Disabled. 1 = Input capture channel 1 Enabled.
4	CAPEN0	Input capture 0 enable 0 = Input capture channel 0 Disabled. 1 = Input capture channel 0 Enabled.
2	CAPF2	Input capture 2 flag This bit is set by hardware if the determined edge of input capture 2 occurs. This bit should cleared by software.
1	CAPF1	Input capture 1 flag This bit is set by hardware if the determined edge of input capture 1 occurs. This bit should cleared by software.
0	CAPF0	Input capture 0 flag This bit is set by hardware if the determined edge of input capture 0 occurs. This bit should cleared by software.

CAPCON1 – Input Capture Control 1

7	6	5	4	3	2	1	0
-	-	CAP2LS[1:0]		CAP1LS[1:0]		CAP0LS[1:0]	
-	-	R/W		R/W		R/W	

Address: 93H Reset value: 0000 0000b

Bit	Name	Description
5:4	CAP2LS[1:0]	Input capture 2 level select 00 = Falling edge. 01 = Rising edge. 10 = Either Rising or falling edge. 11 = Reserved.

Bit	Name	Description
3:2	CAP1LS[1:0]	Input capture 1 level select 00 = Falling edge. 01 = Rising edge. 10 = Either Rising or falling edge. 11 = Reserved.
1:0	CAP0LS[1:0]	Input capture 0 level select 00 = Falling edge. 01 = Rising edge. 10 = Either Rising or falling edge. 11 = Reserved.

CAPCON2 – Input Capture Control 2

7	6	5	4	3	2	1	0
-	ENF2	ENF1	ENF0	-	-	-	-
-	R/W	R/W	R/W	-	-	-	-

Address: 94H Reset value: 0000 0000b

Bit	Name	Description
6	ENF2	Enable noise filter on input capture 2 0 = Noise filter on input capture channel 2 Disabled. 1 = Noise filter on input capture channel 2 Enabled.
5	ENF1	Enable noise filter on input capture 1 0 = Noise filter on input capture channel 1 Disabled. 1 = Noise filter on input capture channel 1 Enabled.
4	ENF0	Enable noise filter on input capture 0 0 = Noise filter on input capture channel 0 Disabled. 1 = Noise filter on input capture channel 0 Enabled.

CKDIV – Clock Divider

7	6	5	4	3	2	1	0
CKDIV[7:0]							
R/W							

Address: 95H Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:0	CKDIV[7:0]	<p>Clock divider</p> <p>The system clock frequency F_{SYS} follows the equation below according to CKDIV value.</p> <p>$F_{SYS} = F_{OSC}$, while CKDIV = 00H, and</p> <p>$F_{SYS} = \frac{F_{OSC}}{2 \times CKDIV}$, while CKDIV = 01H to FFH.</p>

CKSWT – Clock Switch (TA protected)

7	6	5	4	3	2	1	0
-	-	HIRCST	LIRCST	ECLKST	OSC[1:0]		-
-	-	R	R	R	W		-

Address: 96H Reset value: 0011 0000b

Bit	Name	Description
7	-	Reserved
6	-	Reserved
5	HIRCST	<p>High-speed internal oscillator 16 MHz status</p> <p>0 = High-speed internal oscillator is not stable or disabled.</p> <p>1 = High-speed internal oscillator is enabled and stable.</p>
-	-	Reserved
3	ECLKST	<p>External clock input status</p> <p>0 = External clock input is not stable or disabled.</p> <p>1 = External clock input is enabled and stable.</p>
2:1	OSC[1:0]	<p>Oscillator selection bits</p> <p>This field selects the system clock source.</p> <p>00 = Internal 16 MHz oscillator.</p> <p>01 = External clock source according to EXTEN[1:0] (CKEN[7:6]) setting.</p> <p>10 = Internal 10 kHz oscillator.</p> <p>11 = Reserved.</p> <p>Note that this field is write only. The read back value of this field may not correspond to the present system clock source.</p>

CKEN – Clock Enable (TA protected)

7	6	5	4	3	2	1	0
EXTEN[1:0]		HIRCEN	-	-	-	-	CKSWTF
R/W		R/W	-	-	-	-	R

Address: 97H Reset value: 0011 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:6	EXTEN[1:0]	External clock source enable 11 = External clock input via XIN Enabled. Others = external clock input is disable. P30 work as general purpose I/O.
5	HIRCEN	High-speed internal oscillator 16 MHz enable 0 = The high-speed internal oscillator Disabled. 1 = The high-speed internal oscillator Enabled. Note that once IAP is enabled by setting IAPEN (CHPCON.0), the high-speed internal 16 MHz oscillator will be enabled automatically. The hardware will also set HIRCEN and HIRCST bits. After IAPEN is cleared, HIRCEN and EHRST resume the original values.
4:1	-	Reserved
0	CKSWTF	Clock switch fault flag 0 = The previous system clock source switch was successful. 1 = User tried to switch to an instable or disabled clock source at the previous system clock source switch. If switching to an instable clock source, this bit remains 1 until the clock source is stable and switching is successful.

SCON – Serial Port Control (Bit-addressable)

7	6	5	4	3	2	1	0
SM0/FE	SM1	SM2	REN	TB8	RB8	TI	RI
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 98H Reset value: 0000 0000b

Bit	Name	Description
7	SM0/FE	Serial port mode select
6	SM1	<p><u>SMOD0 (PCON.6) = 0:</u> See Table 14.5-1 Serial Port UART0 Mode / baudrate Description for details.</p> <p><u>SMOD0 (PCON.6) = 1:</u> SM0/FE bit is used as frame error (FE) status flag. It is cleared by software. 0 = Frame error (FE) did not occur. 1 = Frame error (FE) occurred and detected.</p>

Bit	Name	Description
5	SM2	<p>Multiprocessor communication mode enable</p> <p>The function of this bit is dependent on the serial port 0 mode.</p> <p><u>Mode 0:</u></p> <p>This bit select the baud rate between $F_{SYS}/12$ and $F_{SYS}/2$.</p> <p>0 = The clock runs at $F_{SYS}/12$ baud rate. It maintains standard 8051 compatibility.</p> <p>1 = The clock runs at $F_{SYS}/2$ baud rate for faster serial communication.</p> <p><u>Mode 1:</u></p> <p>This bit checks valid stop bit.</p> <p>0 = Reception is always valid no matter the logic level of stop bit.</p> <p>1 = Reception is valid only when the received stop bit is logic 1 and the received data matches "Given" or "Broadcast" address.</p> <p><u>Mode 2 or 3:</u></p> <p>For multiprocessor communication.</p> <p>0 = Reception is always valid no matter the logic level of the 9th bit.</p> <p>1 = Reception is valid only when the received 9th bit is logic 1 and the received data matches "Given" or "Broadcast" address.</p>
4	REN	<p>Receiving enable</p> <p>0 = Serial port 0 reception Disabled.</p> <p>1 = Serial port 0 reception Enabled in Mode 1,2, or 3. In Mode 0, reception is initiated by the condition $REN = 1$ and $RI = 0$.</p>
3	TB8	<p>9th transmitted bit</p> <p>This bit defines the state of the 9th transmission bit in serial port 0 Mode 2 or 3. It is not used in Mode 0 or 1</p>
2	RB8	<p>9th received bit</p> <p>The bit identifies the logic level of the 9th received bit in serial port 0 Mode 2 or 3. In Mode 1, RB8 is the logic level of the received stop bit. SM2 bit as logic 1 has restriction for exception. RB8 is not used in Mode 0.</p>
1	TI	<p>Transmission interrupt flag</p> <p>This flag is set by hardware when a data frame has been transmitted by the serial port 0 after the 8th bit in Mode 0 or the last data bit in other modes. When the serial port 0 interrupt is enabled, setting this bit causes the CPU to execute the serial port 0 interrupt service routine. This bit should be cleared manually via software.</p>
0	RI	<p>Receiving interrupt flag</p> <p>This flag is set via hardware when a data frame has been received by the serial port 0 after the 8th bit in Mode 0 or after sampling the stop bit in Mode 1, 2, or 3. SM2 bit as logic 1 has restriction for exception. When the serial port 0 interrupt is enabled, setting this bit causes the CPU to execute to the serial port 0 interrupt service routine. This bit should be cleared manually via software.</p>

SBUF – Serial Port 0 Data Buffer

7	6	5	4	3	2	1	0
SBUF[7:0]							
R/W							

Address: 99H Reset value: 0000 0000b

Bit	Name	Description
7:0	SBUF[7:0]	Serial port 0 data buffer This byte actually consists two separate registers. One is the receiving register, and the other is the transmitting buffer. When data is moved to SBUF, it goes to the transmitting buffer and is shifted for serial transmission. When data is moved from SBUF, it comes from the receiving register. The transmission is initiated through giving data to SBUF.

SBUF_1 – Serial Port 1 Data Buffer

7	6	5	4	3	2	1	0
SBUF_1[7:0]							
R/W							

Address: 9AH Reset value: 0000 0000b

Bit	Name	Description
7:0	SBUF_1[7:0]	Serial port 1 data buffer This byte actually consists two separate registers. One is the receiving register, and the other is the transmitting buffer. When data is moved to SBUF_1, it goes to the transmitting buffer and is shifted for serial transmission. When data is moved from SBUF_1, it comes from the receiving register. The transmission is initiated through giving data to SBUF_1.

EIE – Extensive Interrupt Enable

7	6	5	4	3	2	1	0
ET2	ESPI	EFB	EWDT	EPWM	ECAP	EPI	EI2C
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 9BH Reset value: 0000 0000b

Bit	Name	Description
7	ET2	Enable Timer 2 interrupt 0 = Timer 2 interrupt Disabled. 1 = Interrupt generated by TF2 (T2CON.7) Enabled.
6	ESPI	Enable SPI interrupt 0 = SPI interrupt Disabled. 1 = Interrupt generated by SPIF (SPSR.7), SPIOVF (SPSR.5), or MODF (SPSR.4) Enable.
5	EFB	Enable Fault Brake interrupt 0 = Fault Brake interrupt Disabled. 1 = Interrupt generated by FBF (FBD.7) Enabled.
4	EWDT	Enable WDT interrupt 0 = WDT interrupt Disabled. 1 = Interrupt generated by WDTF (WDCON.5) Enabled.

Bit	Name	Description
3	EPWM	Enable PWM interrupt 0 = PWM interrupt Disabled. 1 = Interrupt generated by PWMF (PWMCON0.5) Enabled.
2	ECAP	Enable input capture interrupt 0 = Input capture interrupt Disabled. 1 = Interrupt generated by any flags of CAPF[2:0] (CAPCON0[2:0]) Enabled.
1	EPI	Enable pin interrupt 0 = Pin interrupt Disabled. 1 = Interrupt generated by any flags in PIF register Enabled.
0	EI2C	Enable I ² C interrupt 0 = I ² C interrupt Disabled. 1 = Interrupt generated by SI (I2CON.3) or I2TOF (I2TOC.0) Enabled.

EIE1 – Extensive Interrupt Enable 1

7	6	5	4	3	2	1	0
-	-	-	-	-	EWKT	ET3	ES_1
-	-	-	-	-	R/W	R/W	R/W

Address: 9CH Reset value: 0000 0000b

Bit	Name	Description
2	EWKT	Enable WKT interrupt 0 = WKT interrupt Disabled. 1 = Interrupt generated by WKTF (WKCON.4) Enabled.
1	ET3	Enable Timer 3 interrupt 0 = Timer 3 interrupt Disabled. 1 = Interrupt generated by TF3 (T3CON.4) Enabled.
0	ES_1	Enable serial port 1 interrupt 0 = Serial port 1 interrupt Disabled. 1 = Interrupt generated by TI_1 (SCON_1.1) or RI_1 (SCON_1.0) Enabled.

CHPCON – Chip Control (TA protected)

7	6	5	4	3	2	1	0
SWRST	IAPFF	-	-	-	-	BS	IAPEN
W	R/W	-	-	-	-	R/W	R/W

Address: 9FH, all pages Reset value: Software 0000 00U0b, Others 0000 00C0b

Bit	Name	Description
6	IAPFF	IAP fault fla

Bit	Name	Description
		<p>The hardware will set this bit after IAPGO (ISPTRG.0) is set if any of the following condition is met:</p> <p>(1) The accessing address is oversize.</p> <p>(2) IAPCN command is invalid.</p> <p>(3) IAP erases or programs updating un-enabled block.</p> <p>(4) IAP erasing or programming operates under V_{BOD} while BOIAP (CONFIG2.5) remains un-programmed 1 with BODEN (BODCON0.7) as 1 and BORST (BODCON0.2) as 0.</p> <p>This bit should be cleared via software.</p>
0	IAPEN	<p>IAP enable</p> <p>0 = IAP function Disabled.</p> <p>1 = IAP function Enabled.</p> <p>Once enabling IAP function, the HIRC will be turned on for timing control. To clear IAPEN should always be the last instruction after IAP operation to stop internal oscillator if reducing power consumption is concerned.</p>
1	BS	<p>Boot select</p> <p>This bit defines from which block that MCU re-boots after all resets.</p> <p>0 = MCU will re-boot from APROM after all resets.</p> <p>1 = MCU will re-boot from LDROM after all resets.</p>
0	IAPEN	<p>IAP enable</p> <p>0 = IAP function Disabled.</p> <p>1 = IAP function Enabled.</p> <p>Once enabling IAP function, the HIRC will be turned on for timing control. To clear IAPEN should always be the last instruction after IAP operation to stop internal oscillator if reducing power consumption is concerned.</p>

P2 – Port 2 (Bit-addressable)

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	P2.0
R	R	R	R	R	R	R	R

Address: A0H Reset value: 0000 000Xb

Bit	Name	Description
7:1	0	<p>Reserved</p> <p>The bits are always read as 0.</p>
0	P2.0	<p>Port 2 bit 0</p> <p>P2.0 is an input-only pin when RPD (CONFIG0.2) is programmed as 0. When leaving RPD un-programmed, P2.0 is always read as 0.</p>

AUXR1 – Auxiliary Register 1

7	6	5	4	3	2	1	0
SWRF	RSTPINF	HardF	-	GF2	UART0PX	0	DPS
R/W	R/W	R/W	-	R/W	R/W	R	R/W

Address: A2H Reset value: POR 0000 0000b, Software 1U00 0000b, nRESET pin U100 0000b, Others UUU0 0000b

Bit	Name	Description
7	SWRF	Software reset flag When the MCU is reset via software reset, this bit will be set via hardware. It is recommended that the flag be cleared via software.
6	RSTPINF	External reset flag When the MCU is reset by the external reset pin, this bit will be set via hardware. It is recommended that the flag be cleared via software.
5	HardF	Hard Fault reset flag Once Program Counter (PC) is over flash size, MCU will be reset and this bit will be set via hardware. It is recommended that the flag be cleared via software. Note: If MCU run in OCD debug mode and OCDEN = 0, hard fault reset will be disabled and only HardF flag be asserted.
3	GF2	General purpose flag 2 The general purpose flag that can be set or cleared by the user via software.
2	UART0PX	Serial port 0 pin exchange 0 = Assign RXD to P0.7 and TXD to P0.6 by default. 1 = Exchange RXD to P0.6 and TXD to P0.7. Note that TXD and RXD will exchange immediately once setting or clearing this bit. User should take care of not exchanging pins during transmission or receiving. Or it may cause unpredictable situation and no warning alarms.
1	0	Reserved This bit is always read as 0.
0	DPS	Data pointer select 0 = Data pointer 0 (DPTR) is active by default. 1 = Data pointer 1 (DPTR1) is active. After DPS switches the activated data pointer, the previous inactivated data pointer remains its original value unchanged.

BODCON0 – Brown-out Detection Control 0 (TA protected)

7	6	5	4	3	2	1	0
BODEN ^[1]		BOV[1:0] ^[1]		BOF ^[2]	BORST ^[1]	BORF	BOS
R/W		R/W		R/W	R/W	R/W	R

Address: A3H Reset value: POR,CCCC XC0Xb / BOD, UUUU XU1Xb / Others,UUUU XUUXb

Bit	Name	Description
7	BODEN	Brown-out detection enable 0 = Brown-out detection circuit off. 1 = Brown-out detection circuit on. Note that BOD output is not available until 2~3 LIRC clocks after enabling.

Bit	Name	Description
6:4	BOV[1:0]	Brown-out voltage select 11 = V_{BOD} is 2.2V. 10 = V_{BOD} is 2.7V. 01 = V_{BOD} is 3.7V. 00 = V_{BOD} is 4.4V.
3	BOF	Brown-out interrupt flag This flag will be set as logic 1 via hardware after a V_{DD} dropping below or rising above V_{BOD} event occurs. If both EBOD (EIE.2) and EA (IE.7) are set, a brown-out interrupt requirement will be generated. This bit should be cleared via software.
2	BORST	Brown-out reset enable This bit decides whether a brown-out reset is caused by a power drop below V_{BOD} . 0 = Brown-out reset when V_{DD} drops below V_{BOD} Disabled. 1 = Brown-out reset when V_{DD} drops below V_{BOD} Enabled.
1	BORF	Brown-out reset flag When the MCU is reset by brown-out event, this bit will be set via hardware. This flag is recommended to be cleared via software.
0	BOS	Brown-out status This bit indicates the V_{DD} voltage level comparing with V_{BOD} while BOD circuit is enabled. It keeps 0 if BOD is not enabled. 0 = V_{DD} voltage level is higher than V_{BOD} or BOD is disabled. 1 = V_{DD} voltage level is lower than V_{BOD} . Note that this bit is read-only.

Note:

1. BODEN, BOV[1:0], and BORST are initialized by being directly loaded from CONFIG2 bit 7, [6:4], and 2 after all resets.
2. BOF reset value depends on different setting of CONFIG2 and V_{DD} voltage level. Please check Table 25.2-1 BOF Reset Value

IAPTRG – IAP Trigger (TA protected)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	IAPGO
-	-	-	-	-	-	-	W

Address: A4H Reset value: 0000 0000b

Bit	Name	Description
0	IAPGO	IAP go IAP begins by setting this bit as logic 1. After this instruction, the CPU holds the Program Counter (PC) and the IAP hardware automation takes over to control the progress. After IAP action completed, the Program Counter continues to run the following instruction. The IAPGO bit will be automatically cleared and always read as logic 0. Before triggering an IAP action, interrupts (if enabled) should be temporary disabled for hardware limitation.

IAPUEN – IAP Updating Enable (TA protected)

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

-	-	-	-	-	CFUEN	LDUEN	APUEN
-	-	-	-	-	R/W	R/W	R/W

Address: A5H Reset value: 0000 0000b

Bit	Name	Description
2	CFUEN	CONFIG bytes updated enable 0 = Inhibit erasing or programming CONFIG bytes by IAP. 1 = Allow erasing or programming CONFIG bytes by IAP.
1	LDUEN	LDROM updated enable 0 = Inhibit erasing or programming LDROM by IAP. 1 = Allow erasing or programming LDROM by IAP.
0	APUEN	APROM updated enable 0 = Inhibit erasing or programming APROM by IAP. 1 = Allow erasing or programming APROM by IAP.

IAPAL – IAP Address Low Byte

7	6	5	4	3	2	1	0
IAPA[7:0]							
R/W							

Address: A6H Reset value: 0000 0000b

Bit	Name	Description
7:0	IAPA[7:0]	IAP address low byte IAPAL contains address IAPA[7:0] for IAP operations.

IAPAH – IAP Address High Byte

7	6	5	4	3	2	1	0
IAPA[15:8]							
R/W							

Address: A7H Reset value: 0000 0000b

Bit	Name	Description
7:0	IAPA[15:8]	IAP address high byte IAPAH contains address IAPA[15:8] for IAP operations.

IE – Interrupt Enable (Bit-addressable)

7	6	5	4	3	2	1	0
EA	EADC	EBOD	ES	ET1	EX1	ET0	EX0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: A8H Reset value: 0000 0000b

Bit	Name	Description
7	EA	Enable all interrupt This bit globally enables/disables all interrupts that are individually enabled. 0 = All interrupt sources Disabled. 1 = Each interrupt Enabled depending on its individual mask setting. Individual interrupts will occur if enabled.
6	EADC	Enable ADC interrupt 0 = ADC interrupt Disabled. 1 = Interrupt generated by ADCF (ADCCON0.7) Enabled.
5	EBOD	Enable brown-out interrupt 0 = Brown-out detection interrupt Disabled. 1 = Interrupt generated by BOF (BODCON0.3) Enabled.
4	ES	Enable serial port 0 interrupt 0 = Serial port 0 interrupt Disabled. 1 = Interrupt generated by TI (SCON.1) or RI (SCON.0) Enabled.
3	ET1	Enable Timer 1 interrupt 0 = Timer 1 interrupt Disabled. 1 = Interrupt generated by TF1 (TCON.7) Enabled.
2	EX1	Enable external interrupt 1 0 = External interrupt 1 Disabled. 1 = Interrupt generated by $\overline{\text{INT1}}$ pin (P1.7) Enabled.
1	ET0	Enable Timer 0 interrupt 0 = Timer 0 interrupt Disabled. 1 = Interrupt generated by TF0 (TCON.5) Enabled.
0	EX0	Enable external interrupt 0 0 = External interrupt 0 Disabled. 1 = Interrupt generated by $\overline{\text{INT0}}$ pin (P3.0) Enabled.

SADDR – Slave 0 Address

7	6	5	4	3	2	1	0
SADDR[7:0]							
R/W							

Address: A9H Reset value: 0000 0000b

Bit	Name	Description
7:0	SADDR[7:0]	Slave 0 address This byte specifies the microcontroller's own slave address for UATR0 multi-processor communication.

WDCON – Watchdog Timer Control (TA protected)

7	6	5	4	3	2	1	0
WDTR	WDCLR	WDTF	WIDPD	WDTRF	WDPS[2:0]		
R/W	R/W	R/W	R/W	R/W	R/W		

Address: AAH Reset value: POR 0000 0111b, WDT 0000 1UUUb, Others 0000 UUUUb

Bit	Name	Description
7	WDTR	WDT run This bit is valid only when control bits in WDTE[3:0] (CONFIG4[7:4]) are all 1. At this time, WDT works as a general purpose timer. 0 = WDT Disabled. 1 = WDT Enabled. The WDT counter starts running.
6	WDCLR	WDT clear Setting this bit will reset the WDT count to 00H. It puts the counter in a known state and prohibit the system from unpredictable reset. The meaning of writing and reading WDCLR bit is different. <u>Writing:</u> 0 = No effect. 1 = Clearing WDT counter. <u>Reading:</u> 0 = WDT counter is completely cleared. 1 = WDT counter is not yet cleared.
5	WDTF	WDT time-out flag This bit indicates an overflow of WDT counter. This flag should be cleared by software.
4	WIDPD	WDT running in Idle or Power-down mode This bit is valid only when control bits in WDTE[3:0] (CONFIG4[7:4]) are all 1. It decides whether WDT runs in Idle or Power-down mode when WDT works as a general purpose timer. 0 = WDT stops running during Idle or Power-down mode. 1 = WDT keeps running during Idle or Power-down mode.
3	WDTRF	WDT reset flag When the MCU is reset by WDT time-out event, this bit will be set via hardware. It is recommended that the flag be cleared via software.
2:0	WDPS[2:0]	WDT clock pre-scalar select These bits determine the pre-scale of WDT clock from 1/1 through 1/256.

Note:

1. WDTRF will be cleared after power-on reset, be set after WDT reset, and remains unchanged after any other resets.
2. WDPS[2:0] are all set after power-on reset and keep unchanged after any reset other than power-on reset.

BODCON1 – Brown-out Detection Control 1 (TA protected)

7	6	5	4	3	2	1	0
-	-	-	-	-	LPBOD[1:0]		BODFLT
-	-	-	-	-	R/W		R/W

Address: ABH Reset value: POR 0000 0001b, Others 0000 0UUUb

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:3	-	Reserved
2:1	LPBOD[1:0]	Low power BOD enable 00 = BOD normal mode. BOD circuit is always enabled. 01 = BOD low power mode 1 by turning on BOD circuit every 1.6 ms periodically. 10 = BOD low power mode 2 by turning on BOD circuit every 6.4 ms periodically. 11 = BOD low power mode 3 by turning on BOD circuit every 25.6 ms periodically.
0	BODFLT	BOD filter control BOD has a filter which counts 32 clocks of F_{SYS} to filter the power noise when MCU runs with HIRC, or ECLK as the system clock and BOD does not operates in its low power mode (LPBOD[1:0] = [0, 0]). In other conditions, the filter counts 2 clocks of LIRC. Note that when CPU is halted in Power-down mode. The BOD output is permanently filtered by 2 clocks of LIRC. The BOD filter avoids the power noise to trigger BOD event. This bit controls BOD filter enabled or disabled. 0 = BOD filter Disabled. 1 = BOD filter Enabled. (Power-on reset default value.)

P3M1 – Port 3 Mode Select 1

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	P3M1.0 ^[3]
-	-	-	-	-	-	-	R/W

Address: ACH, Page: 0 Reset value: 0000 0001b

Bit	Name	Description
0	P3M1.0	Port 3 mode select 1 NOTE: PxM1 and PxM2 are used in combination to determine the I/O mode of each pin of Port. See Table 8.1-1 Configuration for Different I/O Modes .

P3S – Port 3 Schmitt Triggered Input

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	P3S.0
-	-	-	-	-	-	-	R/W

Address: ACH, Page: 1 Reset value: 0000 0000b

Bit	Name	Description
0	P3S.0	P3.0 Schmitt triggered input 0 = TTL level input of P3.0. 1 = Schmitt triggered input of P3.0.

P3M2 – Port 3 Mode Select 2

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	P3M2.0 ^[3]

-	-	-	-	-	-	-	R/W
---	---	---	---	---	---	---	-----

Address: ADH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
0	P3M2.0	Port 3 mode select 2 NOTE: PxM1 and PxM2 are used in combination to determine the I/O mode of each pin of Port. See Table 8.1-1 Configuration for Different I/O Modes .

P3SR – Port 3 Slew Rate

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	P3SR.0
-	-	-	-	-	-	-	R/W

Address: ADH, Page: 1 Reset value: 0000 0000b

Bit	Name	Description
0	P3SR.0	P3.n slew rate 0 = P3.0 normal output slew rate. 1 = P3.0 high-speed output slew rate.

IAPFD – IAP Flash Data

7	6	5	4	3	2	1	0
IAPFD[7:0]							
R/W							

Address: AEH Reset value: 0000 0000b

Bit	Name	Description
7:0	IAPFD[7:0]	IAP flash data This byte contains flash data, which is read from or is going to be written to the Flash Memory. User should write data into IAPFD for program mode before triggering IAP processing and read data from IAPFD for read/verify mode after IAP processing is finished.

IAPCN – IAP Control

7	6	5	4	3	2	1	0
IAPB[1:0]		FOEN	FCEN	FCTRL[3:0]			
R/W		R/W	R/W	R/W			

Address: AFH Reset value: 0011 0000b

Bit	Name	Description
7:6	IAPB[1:0]	IAP control This byte is used for IAP command. For details, see Table 22.1-1 IAP Modes and Command Codes .
5	FOEN	
4	FCEN	

Bit	Name	Description
3:0	FCTRL[3:0]	

P3 – Port 3 (Bit-addressable)

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	P3.0
R	R	R	R	R	R	R	R/W

Address: B0H Reset value: 0000 0001b

Bit	Name	Description
7:1	0	Reserve The bits are always read as 0.
0	P3.0	Port 3 bit 0 P3.0 is available only when the internal oscillator is used as the system clock. At this moment, P3.0 functions as a general purpose I/O. If the system clock is not selected as the internal oscillator, P3.0 pin functions as OSCIN. A write to P3.0 is invalid and P3.0 is always read as 0.

P0M1 – Port 0 Mode Select 1^[1]

7	6	5	4	3	2	1	0
P0M1.7	P0M1.6	P0M1.5	P0M1.4	P0M1.3	P0M1.2	P0M1.1	P0M1.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B1H, Page: 0 Reset value: 1111 1111b

Bit	Name	Description
7:0	P0M1[7:0]	Port 0 mode select 1 NOTE: PxM1 and PxM2 are used in combination to determine the I/O mode of each pin of Port. See Table 8.1-1 Configuration for Different I/O Modes .

P0S – Port 0 Schmitt Triggered Input

7	6	5	4	3	2	1	0
P0S.7	P0S.6	P0S.5	P0S.4	P0S.3	P0S.2	P0S.1	P0S.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B1H, Page: 1 Reset value: 0000 0000b

Bit	Name	Description
n	P0S.n	P0.n Schmitt triggered input 0 = TTL level input of P0.n. 1 = Schmitt triggered input of P0.n.

P0M2 – Port 0 Mode Select 2

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

P0M2.7	P0M2.6	P0M2.5	P0M2.4	P0M2.3	P0M2.2	P0M2.1	P0M2.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B3H, Page: 0 Reset value: 1111 1111b

Bit	Name	Description
7:0	P1M1[7:0]	Port 1 mode select 1 NOTE: PxM1 and PxM2 are used in combination to determine the I/O mode of each pin of Port. See Table 8.1-1 Configuration for Different I/O Modes .

P1S – Port 1 Schmitt Triggered Input

7	6	5	4	3	2	1	0
P1S.7	P1S.6	P1S.5	P1S.4	P1S.3	P1S.2	P1S.1	P1S.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B3H, Page: 1 Reset value: 0000 0000b

Bit	Name	Description
n	P1S.n	P1.n Schmitt triggered input 0 = TTL level input of P1.n. 1 = Schmitt triggered input of P1.n.

P1M2 – Port 1 Mode Select 2

7	6	5	4	3	2	1	0
P1M2.7	P1M2.6	P1M2.5	P1M2.4	P1M2.3	P1M2.2	P1M2.1	P1M2.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B4H, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
7:0	P1M2[7:0]	Port 1 mode select 2. NOTE: PxM1 and PxM2 are used in combination to determine the I/O mode of each pin of Port. See Table 8.1-1 Configuration for Different I/O Modes .

P1SR – Port 1 Slew Rate

7	6	5	4	3	2	1	0
P1SR.7	P1SR.6	P1SR.5	P1SR.4	P1SR.3	P1SR.2	P1SR.1	P1SR.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B4H, Page: 1 Reset value: 0000 0000b

Bit	Name	Description
n	P1SR.n	P1.n slew rate 0 = P1.n normal output slew rate. 1 = P1.n high-speed output slew rate.

P2S – P20 Setting and Timer01 Output Enable

7	6	5	4	3	2	1	0
P20UP	-	-	-	T1OE	T0OE	-	P2S.0
R/W	-	-	-	R/W	R/W	-	R/W

Address: B5H Reset value: 0000 0000b

Bit	Name	Description
7	P20UP	P2.0 pull-up enable 0 = P2.0 pull-up Disabled. 1 = P2.0 pull-up Enabled. This bit is valid only when RPD (CONFIG0.2) is programmed as 0. When selecting as a $\overline{\text{RST}}$ pin, the pull-up is always enabled.
3	T1OE	Timer 1 output enable 0 = Timer 1 output Disabled. 1 = Timer 1 output Enabled from T1 pin. Note that Timer 1 output should be enabled only when operating in its "Timer" mode.
2	T0OE	Timer 0 output enable 0 = Timer 0 output Disabled. 1 = Timer 0 output Enabled from T0 pin. Note that Timer 0 output should be enabled only when operating in its "Timer" mode.

Bit	Name	Description
0	P2S.0	P2.0 Schmitt triggered input 0 = TTL level input of P2.0. 1 = Schmitt triggered input of P2.0.

IPH – Interrupt Priority High^[2]

7	6	5	4	3	2	1	0
-	PADCH	PBODH	PSH	PT1H	PX1H	PT0H	PX0H
-	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B7H, Page0 Reset value: 0000 0000b

Bit	Name	Description
6	PADC	ADC interrupt priority high bit
5	PBOD	Brown-out detection interrupt priority high bit
4	PSH	Serial port 0 interrupt priority high bit
3	PT1H	Timer 1 interrupt priority high bit
2	PX1H	External interrupt 1 priority high bit
1	PT0H	Timer 0 interrupt priority high bit
0	PX0H	External interrupt 0 priority high bit

Note:IPH is used in combination with the IP respectively to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

PWMINTC – PWM Interrupt Control

7	6	5	4	3	2	1	0
-	-	INTTYP1	INTTYP0	-	INTSEL2	INTSEL1	INTSEL0
-	-	R/W	R/W	-	R/W	R/W	R/W

Address: B7H, Page:1 Reset value: 0000 0000b

Bit	Name	Description
5:4	INTTYP[1:0]	PWM interrupt type select These bit select PWM interrupt type. 00 = Falling edge on PWM0 channel 0/1/2/3/4/5 pin. 01 = Rising edge on PWM0 channel 0/1/2/3/4/5 pin. 10 = Central point of a PWM0 period. 11 = End point of a PWM0 period. Note that the central point interrupt or the end point interrupt is only available while PWM operates in center-aligned type.

Bit	Name	Description
2:0	INTSEL[2:0]	<p>PWM interrupt pair select</p> <p>These bits select which PWM channel asserts PWM interrupt when PWM interrupt type is selected as falling or rising edge on PWM0 channel 0~5 pin..</p> <p>000 = PWM0_CH0. 001 = PWM0_CH1. 010 = PWM0_CH2. 011 = PWM0_CH3. 100 = PWM0_CH4. 101 = PWM0_CH5. Others = PWM0_CH0.</p>

IP – Interrupt Priority (Bit-addressable)^[1]

7	6	5	4	3	2	1	0
-	PADC	PBOD	PS	PT1	PX1	PT0	PX0
-	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B8H Reset value: 0000 0000b

Bit	Name	Description
6	PADC	ADC interrupt priority low bit
5	PBOD	Brown-out detection interrupt priority low bit
4	PS	Serial port 0 interrupt priority low bit
3	PT1	Timer 1 interrupt priority low bit
2	PX1	External interrupt 1 priority low bit
1	PT0	Timer 0 interrupt priority low bit
0	PX0	External interrupt 0 priority low bit

Note: IP is used in combination with the IPH to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

SADEN – Slave 0 Address Mask

7	6	5	4	3	2	1	0
SADEN[7:0]							
R/W							

Address: B9H Reset value: 0000 0000b

Bit	Name	Description
7:0	SADEN[7:0]	<p>Slave 0 address mask</p> <p>This byte is a mask byte of UART0 that contains “don’t-care” bits (defined by zeros) to form the device’s “Given” address. The don’t-care bits provide the flexibility to address one or more slaves at a time.</p>

SADEN_1 – Slave 1 Address Mask

7	6	5	4	3	2	1	0
SADEN_1[7:0]							
R/W							

Address: BAH Reset value: 0000 0000b

Bit	Name	Description
7:0	SADEN_1[7:0]	Slave 1 address mask This byte is a mask byte of UART1 that contains “don’t-care” bits (defined by zeros) to form the device’s “Given” address. The don’t-care bits provide the flexibility to address one or more slaves at a time.

SADDR_1 – Slave 1 Address

7	6	5	4	3	2	1	0
SADDR_1[7:0]							
R/W							

Address: BBH Reset value: 0000 0000b

Bit	Name	Description
7:0	SADDR_1[7:0]	Slave 1 address This byte specifies the microcontroller’s own slave address for UART1 multi-processor communication.

I2DAT – I²C Data

7	6	5	4	3	2	1	0
I2DAT[7:0]							
R/W							

Address: BCH Reset value: 0000 0000b

Bit	Name	Description
7:0	I2DAT[7:0]	I ² C data I2DAT contains a byte of the I ² C data to be transmitted or a byte, which has just received. Data in I2DAT remains as long as SI is logic 1. The result of reading or writing I2DAT during I ² C transceiving progress is unpredicted. While data in I2DAT is shifted out, data on the bus is simultaneously being shifted in to update I2DAT. I2DAT always shows the last byte that presented on the I ² C bus. Thus the event of lost arbitration, the original value of I2DAT changes after the transaction.

I2STAT – I²C Status

7	6	5	4	3	2	1	0
I2STAT[7:3]					0	0	0
R					R	R	R

Address: BDH Reset value: 1111 1000b

Bit	Name	Description
7:3	I2STAT[7:3]	I ² C status code The MSB five bits of I2STAT contains the status code. There are 27 possible status codes. When I2STAT is F8H, no relevant state information is available and SI flag keeps 0. All other 26 status codes correspond to the I ² C states. When each of these status is entered, SI will be set as logic 1 and a interrupt is requested.
2:0	0	Reserved The least significant three bits of I2STAT are always read as 0.

I2CLK – I²C Clock

7	6	5	4	3	2	1	0
I2CLK[7:0]							
R/W							

Address: BEH Reset value: 0000 1001b

Bit	Name	Description
7:0	I2CLK[7:0]	I ² C clock setting <u>In master mode:</u> This register determines the clock rate of I ² C bus when the device is in a master mode. The clock rate follows the equation, $\frac{F_{SYS}}{4 \times (I2CLK + 1)}$ The default value will make the clock rate of I ² C bus 400k bps if the peripheral clock is 16 MHz. Note that the I2CLK value of 00H and 01H are not valid. This is an implement limitation. <u>In slave mode:</u> This byte has no effect. In slave mode, the I ² C device will automatically synchronize with any given clock rate up to 400k bps.

I2TOC – I²C Time-out Counter

7	6	5	4	3	2	1	0
-	-	-	-	-	I2TOCEN	DIV	I2TOF
-	-	-	-	-	R/W	R/W	R/W

Address: BFH Reset value: 0000 0000b

Bit	Name	Description
2	I2TOCEN	I ² C time-out counter enable 0 = I ² C time-out counter Disabled. 1 = I ² C time-out counter Enabled.

Bit	Name	Description
1	DIV	I ² C time-out counter clock divider 0 = The clock of I ² C time-out counter is F _{SYS} /1. 1 = The clock of I ² C time-out counter is F _{SYS} /4.
0	I2TOF	I ² C time-out flag This flag is set by hardware if 14-bit I ² C time-out counter overflows. It is cleared by software.

I2CON – I²C Control (Bit-addressable)

7	6	5	4	3	2	1	0
-	I2CEN	STA	STO	SI	AA	-	I2CPX
-	R/W	R/W	R/W	R/W	R/W	-	R/W

Address: C0H Reset value: 0000 0000b

Bit	Name	Description
6	I2CEN	I ² C bus enable 0 = I ² C bus Disabled. 1 = I ² C bus Enabled. Before enabling the I ² C, I2C0_SCL and I2C0_SDA port latches should be set to logic 1.
5	STA	START flag When STA is set, the I ² C generates a START condition if the bus is free. If the bus is busy, the I ² C waits for a STOP condition and generates a START condition following. If STA is set while the I ² C is already in the master mode and one or more bytes have been transmitted or received, the I ² C generates a repeated START condition. Note that STA can be set anytime even in a slave mode, but STA is not hardware automatically cleared after START or repeated START condition has been detected. User should take care of it by clearing STA manually.
4	STO	STOP flag When STO is set if the I ² C is in the master mode, a STOP condition is transmitted to the bus. STO is automatically cleared by hardware once the STOP condition has been detected on the bus. The STO flag setting is also used to recover the I ² C device from the bus error state (I2STAT as 00H). In this case, no STOP condition is transmitted to the I ² C bus. If the STA and STO bits are both set and the device is original in the master mode, the I ² C bus will generate a STOP condition and immediately follow a START condition. If the device is in slave mode, STA and STO simultaneous setting should be avoid from issuing illegal I ² C frames.

Bit	Name	Description
3	SI	<p>I^2C interrupt flag</p> <p>SI flag is set by hardware when one of 26 possible I^2C status (besides F8H status) is entered. After SI is set, the software should read I2STAT register to determine which step has been passed and take actions for next step.</p> <p>SI is cleared by software. Before the SI is cleared, the low period of I2C0_SCL line is stretched. The transaction is suspended. It is useful for the slave device to deal with previous data bytes until ready for receiving the next byte.</p> <p>The serial transaction is suspended until SI is cleared by software. After SI is cleared, I^2C bus will continue to generate START or repeated START condition, STOP condition, 8-bit data, or so on depending on the software configuration of controlling byte or bits. Therefore, user should take care of it by preparing suitable setting of registers before SI is software cleared.</p>
2	AA	<p>Acknowledge assert flag</p> <p>If the AA flag is set, an ACK (low level on I2C0_SDA) will be returned during the acknowledge clock pulse of the I2C0_SCL line while the I^2C device is a receiver or an own-address-matching slave.</p> <p>If the AA flag is cleared, a NACK (high level on I2C0_SDA) will be returned during the acknowledge clock pulse of the I2C0_SCL line while the I^2C device is a receiver or an own-address-matching slave. A device with its own AA flag cleared will ignore its own slave address and the General Call. Consequently, SI will not be asserted and no interrupt is requested.</p> <p>Note that if an addressed slave does not return an ACK under slave receiver mode or not receive an ACK under slave transmitter mode, the slave device will become a not addressed slave. It cannot receive any data until its AA flag is set and a master addresses it again.</p> <p>There is a special case of I2STAT value C8H occurs under slave transmitter mode. Before the slave device transmit the last data byte to the master, AA flag can be cleared as 0. Then after the last data byte transmitted, the slave device will actively switch to not addressed slave mode of disconnecting with the master. The further reading by the master will be all FFH.</p>
0	I2CPX	<p>I2C pins select</p> <p>0 = Assign I2C0_SCL to P1.3 and I2C0_SDA to P1.4.</p> <p>1 = Assign I2C0_SCL to P0.2 and I2C0_SDA to P1.6.</p> <p>Note that I2C pins will exchange immediately once setting or clearing this bit.</p>

I2ADDR – I^2C Own Slave Address

7	6	5	4	3	2	1	0
I2ADDR[7:1]							GC
R/W							R/W

Address: C1H Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:1	I2ADDR[7:1]	<p>I²C device's own slave address</p> <p><u>In master mode:</u> These bits have no effect.</p> <p><u>In slave mode:</u> These 7 bits define the slave address of this I²C device by user. The master should address I²C device by sending the same address in the first byte data after a START or a repeated START condition. If the AA flag is set, this I²C device will acknowledge the master after receiving its own address and become an addressed slave. Otherwise, the addressing from the master will be ignored.</p> <p>Note that I2ADDR[7:1] should not remain its default value of all 0, because address 0x00 is reserved for General Call.</p>
6	GC	<p>General Call bit</p> <p><u>In master mode:</u> This bit has no effect.</p> <p><u>In slave mode:</u> 0 = The General Call is always ignored. 1 = The General Call is recognized if AA flag is 1; otherwise, it is ignored if AA is 0.</p>

ADCRL – ADC Result Low Byte

7	6	5	4	3	2	1	0
-	-	-	-	ADCR[3:0]			
-	-	-	-	R			

Address: C2H Reset value: 0000 0000b

Bit	Name	Description
3:0	ADCR[3:0]	<p>ADC result low byte</p> <p>The least significant 4 bits of the ADC result stored in this register.</p>

ADCRH – ADC Result High Byte

7	6	5	4	3	2	1	0
ADCR[11:4]							
R							

Address: C3H Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCR[11:4]	<p>ADC result high byte</p> <p>The most significant 8 bits of the ADC result stored in this register.</p>

T3CON – Timer 3 Control

7	6	5	4	3	2	1	0
SMOD_1	SMOD0_1	BRCK	TF3	TR3	T3PS[2:0]		

R/W	R/W	R/W	R/W	R/W	R/W
-----	-----	-----	-----	-----	-----

Address: C4H, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7	SMOD_1	Serial port 1 double baud rate enable Setting this bit doubles the serial port baud rate when UART1 is in Mode 2. See Table 14.5-2 Serial Port UART1 Mode / baudrate Description for details.
6	SMOD0_1	Serial port 1 framing error access enable 0 = SCON_1.7 accesses to SM0_1 bit. 1 = SCON_1.7 accesses to FE_1 bit.
5	BRCK	Serial port 0 baud rate clock source This bit selects which Timer is used as the baud rate clock source when serial port 0 is in Mode 1 or 3. 0 = Timer 1. 1 = Timer 3.
4	TF3	Timer 3 overflow flag This bit is set when Timer 3 overflows. It is automatically cleared by hardware when the program executes the Timer 3 interrupt service routine. This bit can be set or cleared by software.
3	TR3	Timer 3 run control 0 = Timer 3 is halted. 1 = Timer 3 starts running. Note that the reload registers RH3 and RL3 can only be written when Timer 3 is halted (TR3 bit is 0). If any of RH3 or RL3 is written if TR3 is 1, result is unpredictable.
2:0	T3PS[2:0]	Timer 3 pre-scalar These bits determine the scale of the clock divider for Timer 3. 000 = 1/1. 001 = 1/2. 010 = 1/4. 011 = 1/8. 100 = 1/16. 101 = 1/32. 110 = 1/64. 111 = 1/128.

PWM4H – PWM4 Duty High Byte

7	6	5	4	3	2	1	0
PWM4[15:8]							
R/W							

Address: C4H, Page:1 reset value: 0000 0000b

Bit	Name	Description
7:0	PWM4[15:8]	PWM4 duty high byte This byte with PWM4L controls the duty of the output signal PG4 from PWM generator.

RL3 – Timer 3 Reload Low Byte

7	6	5	4	3	2	1	0
RL3[7:0]							
R/W							

Address: C5H, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7:0	RL3[7:0]	Timer 3 reload low byte It holds the low byte of the reload value of Timer 3.

PWM5H – PWM0 Channel 5 Duty High Byte

7	6	5	4	3	2	1	0
PWM5[15:8]							
R/W							

Address: C5H, Page:1 Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM5[15:8]	PWM0_CH5 duty high byte This byte with PWM5L controls the duty of the output signal PG5 from PWM generator.

RH3 – Timer 3 Reload High Byte

7	6	5	4	3	2	1	0
RH3[7:0]							
R/W							

Address: C6H, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7:0	RH3[7:0]	Timer 3 reload high byte It holds the high byte of the reload value of Time 3.

PIOCON1 – PWM or I/O Select

7	6	5	4	3	2	1	0
-	-	PIO15	-	PIO13	PIO12	PIO11	-
-	-	R/W	-	R/W	R/W	R/W	-

Address: C6H, Page:1 Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
5	PIO15	P1.5/PWM0_CH5 pin function select 0 = P1.5/PWM0_CH5 pin functions as P1.5. 1 = P1.5/PWM0_CH5 pin functions as PWM0 channel 5 output.
3	PIO13	P0.4/PWM3 pin function select 0 = P0.4/PWM0_CH3 pin functions as P0.4. 1 = P0.4/PWM0_CH3 pin functions as PWM0 channel 3 output.
2	PIO12	P0.5/PWM2 pin function select 0 = P0.5/PWM0_CH2 pin functions as P0.5. 1 = P0.5/PWM0_CH2 pin functions as PWM0 channel 2 output.
1	PIO11	P1.4/PWM0 channel 1 pin function select 0 = P1.4/PWM0_CH1 pin functions as P1.4. 1 = P1.4/PWM0_CH1 pin functions as PWM0 channel 1 output.

TA – Timed Access

7	6	5	4	3	2	1	0
TA[7:0]							
W							

Address: C7H Reset value: 0000 0000b

Bit	Name	Description
7:0	TA[7:0]	Timed access The timed access register controls the access to protected SFRs. To access protected bits, user should first write AAH to the TA and immediately followed by a write of 55H to TA. After these two steps, a writing permission window is opened for 4 clock cycles during this period that user may write to protected SFRs.

T2CON – Timer 2 Control

7	6	5	4	3	2	1	0
TF2	-	-	-	-	TR2	-	CM/RL2
R/W	-	-	-	-	R/W	-	R/W

Address: C8H Reset value: 0000 0000b

Bit	Name	Description
7	TF2	Timer 2 overflow flag This bit is set when Timer 2 overflows or a compare match occurs. If the Timer 2 interrupt and the global interrupt are enable, setting this bit will make CPU execute Timer 2 interrupt service routine. This bit is not automatically cleared via hardware and should be cleared via software.
2	TR2	Timer 2 run control 0 = Timer 2 Disabled. Clearing this bit will halt Timer 2 and the current count will be preserved in TH2 and TL2. 1 = Timer 2 Enabled.

Bit	Name	Description
0	CM/RL2	Timer 2 compare or auto-reload mode select This bit selects Timer 2 functioning mode. 0 = Auto-reload mode. 1 = Compare mode.

T2MOD – Timer 2 Mode

7	6	5	4	3	2	1	0
LDEN	T2DIV[2:0]			CAPCR	CMPCR	LDTS[1:0]	
R/W	R/W			R/W	R/W	R/W	

Address: C9H Reset value: 0000 0000b

Bit	Name	Description
7	LDEN	Enable auto-reload 0 = Reloading RCMP2H and RCMP2L to TH2 and TL2 Disabled. 1 = Reloading RCMP2H and RCMP2L to TH2 and TL2 Enabled.
6:4	T2DIV[2:0]	Timer 2 clock divider 000 = Timer 2 clock divider is 1/1. 001 = Timer 2 clock divider is 1/4. 010 = Timer 2 clock divider is 1/16. 011 = Timer 2 clock divider is 1/32. 100 = Timer 2 clock divider is 1/64. 101 = Timer 2 clock divider is 1/128. 110 = Timer 2 clock divider is 1/256. 111 = Timer 2 clock divider is 1/512.
3	CAPCR	Capture auto-clear This bit is valid only under Timer 2 auto-reload mode. It enables hardware auto-clearing TH2 and TL2 counter registers after they have been transferred in to RCMP2H and RCMP2L while a capture event occurs. 0 = Timer 2 continues counting when a capture event occurs. 1 = Timer 2 value is auto-cleared as 0000H when a capture event occurs.
2	CMPCR	Compare match auto-clear This bit is valid only under Timer 2 compare mode. It enables hardware auto-clearing TH2 and TL2 counter registers after a compare match occurs. 0 = Timer 2 continues counting when a compare match occurs. 1 = Timer 2 value is auto-cleared as 0000H when a compare match occurs.
1:0	LDTS[1:0]	Auto-reload trigger select These bits select the reload trigger event. 00 = Reload when Timer 2 overflows. 01 = Reload when input capture 0 event occurs. 10 = Reload when input capture 1 event occurs. 11 = Reload when input capture 2 event occurs.

RCMP2L – Timer 2 Reload/Compare Low Byte

7	6	5	4	3	2	1	0
RCMP2L[7:0]							
R/W							

Address: CAH Reset value: 0000 0000b

Bit	Name	Description
7:0	RCMP2L[7:0]	Timer 2 reload/compare low byte This register stores the low byte of compare value when Timer 2 is configured in compare mode. Also it holds the low byte of the reload value in auto-reload mode.

RCMP2H – Timer 2 Reload/Compare High Byte

7	6	5	4	3	2	1	0
RCMP2H[7:0]							
R/W							

Address: CBH Reset value: 0000 0000b

Bit	Name	Description
7:0	RCMP2H[7:0]	Timer 2 reload/compare high byte This register stores the high byte of compare value when Timer 2 is configured in compare mode. Also it holds the high byte of the reload value in auto-reload mode.

TL2 – Timer 2 Low Byte

7	6	5	4	3	2	1	0
TL2[7:0]							
R/W							

Address: CCH, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7:0	TL2[7:0]	Timer 2 low byte The TL2 register is the low byte of the 16-bit counting register of Timer 2.

PWM4L – PWM4 Duty Low Byte

7	6	5	4	3	2	1	0
PWM4[7:0]							
R/W							

Address: CCH, Page:1 reset value: 0000 0000b

Bit	Name	Description
7:0	PWM4[7:0]	PWM4 duty low byte This byte with PWM4H controls the duty of the output signal PG4 from PWM generator.

TH2 – Timer 2 High Byte

7	6	5	4	3	2	1	0
TH2[7:0]							
R/W							

Address: CDH, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7:0	TH2[7:0]	Timer 2 high byte The TH2 register is the high byte of the 16-bit counting register of Timer 2.

PWM5L – PWM0_CH5 Duty Low Byte

7	6	5	4	3	2	1	0
PWM5[7:0]							
R/W							

Address: CDH, Page:1 Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM5[7:0]	PWM0_CH5 duty low byte This byte with PWM5H controls the duty of the output signal PG5 from PWM generator.

ADCMP – ADC Compare Low Byte

7	6	5	4	3	2	1	0
-	-	-	-	ADCMP[3:0]			
-	-	-	-	W/R			

Address: CEH Reset value: 0000 0000b

Bit	Name	Description
3:0	ADCMP[3:0]	ADC compare low byte The least significant 4 bits of the ADC compare value stores in this register.

ADCMPH – ADC Compare High Byte

7	6	5	4	3	2	1	0
ADCMP[11:4]							
W/R							

Address: CFH Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCMP[11:4]	ADC compare high byte The most significant 8 bits of the ADC compare value stores in this register.

PSW – Program Status Word (Bit-addressable)

7	6	5	4	3	2	1	0
CY	AC	F0	RS1	RS0	OV	F1	P
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Address: D0H Reset value: 0000 0000b

Bit	Name	Description																				
7	CY	Carry flag For a adding or subtracting operation, CY will be set when the previous operation resulted in a carry-out from or a borrow-in to the Most Significant bit, otherwise cleared. If the previous operation is MUL or DIV, CY is always 0. CY is affected by DA A instruction, which indicates that if the original BCD sum is greater than 100. For a CJNE branch, CY will be set if the first unsigned integer value is less than the second one. Otherwise, CY will be cleared.																				
6	C	Auxiliary carry Set when the previous operation resulted in a carry-out from or a borrow-in to the 4 th bit of the low order nibble, otherwise cleared.																				
5	0	User flag 0 The general purpose flag that can be set or cleared by user.																				
4	RS1	Register bank selection bits																				
3	RS0	These two bits select one of four banks in which R0 to R7 locate. <table><tr><th>RS1</th><th>RS0</th><th>Register Bank</th><th>RAM Address</th></tr><tr><td>0</td><td>0</td><td>0</td><td>00H to 07H</td></tr><tr><td>0</td><td>1</td><td>1</td><td>08H to 0FH</td></tr><tr><td>1</td><td>0</td><td>2</td><td>10H to 17H</td></tr><tr><td>1</td><td>1</td><td>3</td><td>18H to 1FH</td></tr></table>	RS1	RS0	Register Bank	RAM Address	0	0	0	00H to 07H	0	1	1	08H to 0FH	1	0	2	10H to 17H	1	1	3	18H to 1FH
RS1	RS0	Register Bank	RAM Address																			
0	0	0	00H to 07H																			
0	1	1	08H to 0FH																			
1	0	2	10H to 17H																			
1	1	3	18H to 1FH																			
2	V	Overflow flag OV is used for a signed character operands. For a ADD or ADDC instruction, OV will be set if there is a carry out of bit 6 but not out of bit 7, or a carry out of bit 7 but not bit 6. Otherwise, OV is cleared. OV indicates a negative number produced as the sum of two positive operands or a positive sum from two negative operands. For a SUBB, OV is set if a borrow is needed into bit6 but not into bit 7, or into bit7 but not bit 6. Otherwise, OV is cleared. OV indicates a negative number produced when a negative value is subtracted from a positive value, or a positive result when a positive number is subtracted from a negative number. For a MUL, if the product is greater than 255 (00FFH), OV will be set. Otherwise, it is cleared. For a DIV, it is normally 0. However, if B had originally contained 00H, the values returned in A and B will be undefined. Meanwhile, the OV will be set.																				
1	1	User flag 1 The general purpose flag that can be set or cleared by user via software.																				
0	P	Parity flag Set to 1 to indicate an odd number of ones in the accumulator. Cleared for an even number of ones. It performs even parity check.																				

Instruction	CY	OV	AC	Instruction	CY	OV	AC
ADD	X ⁽¹⁾	X	X	CLR C	0		
ADDC	X	X	X	CPL C	X		
SUBB	X	X	X	ANL C, bit	X		
MUL	0	X		ANL C, /bit	X		
DIV	0	X		ORL C, bit	X		
DA A	X			ORL C, /bit	X		
RRC A	X			MOV C, bit	X		
RLC A	X			CJNE	X		
SETB C	1						

Note: X indicates the modification depends on the result of the instruction.

Table 7.2-1 Instructions That Affect Flag Settings

PWMPH – PWM Period High Byte

7	6	5	4	3	2	1	0
PWMP[15:8]							
R/W							

Address: D1H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWMP[15:8]	PWM period high byte This byte with PWMPH controls the period of the PWM generator signal.

PWM0H – PWM0 Duty High Byte

7	6	5	4	3	2	1	0
PWM0[15:8]							
R/W							

Address: D2H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM0[15:8]	PWM0 duty high byte This byte with PWM0L controls the duty of the output signal PG0 from PWM generator.

PWM1H – PWM1 Duty High Byte

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

PWM1[15:8]
R/W

Address: D3H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM1[15:8]	PWM0 channel 1 duty high byte This byte with PWM1L controls the duty of the output signal PG1 from PWM generator.

PWM2H – PWM2 Duty High Byte

7	6	5	4	3	2	1	0
PWM2[15:8]							
R/W							

Address: D4H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM2[15:8]	PWM0 channel 2 duty high byte This byte with PWM2L controls the duty of the output signal PG2 from PWM generator.

PWM3H – PWM3 Duty High Byte

7	6	5	4	3	2	1	0
PWM3[15:8]							
R/W							

Address: D5H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM3[15:8]	PWM0 channel 3 duty high byte This byte with PWM3L controls the duty of the output signal PG3 from PWM generator.

PNP – PWM Negative Polarity

7	6	5	4	3	2	1	0
-	-	PNP5	PNP4	PNP3	PNP2	PNP1	PNP0
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Address: D6H Reset value: 0000 0000b

Bit	Name	Description
n	PNPn	PWMn negative polarity output enable 0 = PWMn signal outputs directly on PWMn pin. 1 = PWMn signal outputs inversely on PWMn pin.

FBD – PWM Fault Brake Data

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

FBF	FBINLS	FBD5	FBD4	FBD3	FBD2	FBD1	FBD0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: D7H Reset value: 0000 0000b

Bit	Name	Description
7	FBF	Fault Brake flag This flag is set when FBINEN is set as 1 and FB pin detects an edge, which matches FBINLS (FBD.6) selection. This bit is cleared by software. After FBF is cleared, Fault Brake data output will not be released until PWMRUN (PWMCON0.7) is set.
6	FBINLS	PWM_BRAKE pin input level selection 0 = Falling edge. 1 = Rising edge.
N	FBDn	PWMn Fault Brake data 0 = PWMn signal is overwritten by 0 once Fault Brake asserted. 1 = PWMn signal is overwritten by 1 once Fault Brake asserted.

PWMCON0 – PWM Control 0 (Bit-addressable)

7	6	5	4	3	2	1	0
PWMRUN	LOAD	PWMF	CLRPWM	-	-	-	-
R/W	R/W	R/W	R/W	-	-	-	-

Address: D8H Reset value: 0000 0000b

Bit	Name	Description
7	PWMRUN	PWM run enable 0 = PWM stays in idle. 1 = PWM starts running.
6	LOAD	PWM new period and duty load This bit is used to load period and duty control registers in their buffer if new period or duty value needs to be updated. The loading will act while a PWM period is completed. The new period and duty affected on the next PWM cycle. After the loading is complete, LOAD will be automatically cleared via hardware. The meaning of writing and reading LOAD bit is different. <u>Writing:</u> 0 = No effect. 1 = Load new period and duty in their buffers while a PWM period is completed. <u>Reading:</u> 0 = A loading of new period and duty is finished. 1 = A loading of new period and duty is not yet finished.
5	PWMF	PWM flag This flag is set according to definitions of INTSEL[2:0] and INTTYP[1:0] in PWMINTC. This bit is cleared by software.

Bit	Name	Description
4	CLRPWM	<p>Clear PWM counter</p> <p>Setting this bit clears the value of PWM 16-bit counter for resetting to 0000H. After the counter value is cleared, CLRPWM will be automatically cleared via hardware. The meaning of writing and reading CLRPWM bit is different.</p> <p><u>Writing:</u></p> <p>0 = No effect. 1 = Clearing PWM 16-bit counter.</p> <p><u>Reading:</u></p> <p>0 = PWM 16-bit counter is completely cleared. 1 = PWM 16-bit counter is not yet cleared.</p>

PWMPL – PWM Period Low Byte

7	6	5	4	3	2	1	0
PWMP[7:0]							
R/W							

Address: D9H Reset value: 0000 0000b

Bit	Name	Description
7:0	PWMP[7:0]	<p>PWM period low byte</p> <p>This byte with PWMPH controls the period of the PWM generator signal.</p>

PWM0L – PWM0 Duty Low Byte

7	6	5	4	3	2	1	0
PWM0[7:0]							
R/W							

Address: DAH Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM0[7:0]	<p>PWM0 Channel 0 duty low byte</p> <p>This byte with PWM0H controls the duty of the output signal PG0 from PWM generator.</p>

PWM1L – PWM/1 Duty Low Byte

7	6	5	4	3	2	1	0
PWM1[7:0]							
R/W							

Address: DBH Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM1[7:0]	<p>PWM0 channel 1 duty low byte</p> <p>This byte with PWM1H controls the duty of the output signal PG1 from PWM generator.</p>

PWM2L – PWM2 Duty Low Byte

7	6	5	4	3	2	1	0
PWM2[7:0]							
R/W							

Address: DCH Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM2[7:0]	PWM0 channel 2 duty low byte This byte with PWM2H controls the duty of the output signal PG2 from PWM generator.

PWM3L – PWM3 Duty Low Byte

7	6	5	4	3	2	1	0
PWM3[7:0]							
R/W							

Address: DDH Reset value: 0000 0000b

Bit	Name	Description
7:0	PWM3[7:0]	PWM0 channel 3 duty low byte This byte with PWM3H controls the duty of the output signal PG3 from PWM generator.

PIOCON0 – PWM or I/O Select

7	6	5	4	3	2	1	0
-	-	PIO05	PIO04	PIO03	PIO02	PIO01	PIO00
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Address: DEH Reset value: 0000 0000b

Bit	Name	Description
5	PIO05	P0.3/PWM0 channel 5 pin function select 0 = P0.3/PWM0_CH5 pin functions as P0.3. 1 = P0.3/PWM0_CH5 pin functions as PWM0_CH5 output.
4	PIO04	P0.1/PWM0 channel 4 pin function select 0 = P0.1/PWM0_CH4 pin functions as P0.1. 1 = P0.1/PWM0_CH4 pin functions as PWM4 output.
3	PIO03	P0.0/PWM0 channel 3 pin function select 0 = P0.0/PWM0_CH3 pin functions as P0.0. 1 = P0.0/PWM0_CH3 pin functions as PWM3 output.
2	PIO02	P1.0/PWM0 channel 2 pin function select 0 = P1.0/PWM0_CH2 pin functions as P1.0. 1 = P1.0/PWM0_CH2 pin functions as PWM2 output.

Bit	Name	Description
1	PIO01	P1.1/PWM0 channel 1 pin function select 0 = P1.1/PWM0_CH1 pin functions as P1.1. 1 = P1.1/PWM0_CH1 pin functions as PWM1 output.
0	PIO00	P1.2/PWM0 channel 0 pin function select 0 = P1.2/PWM0_CH0 pin functions as P1.2. 1 = P1.2/PWM0_CH0 pin functions as PWM0 output.

PWMCON1 – PWM Control 1

7	6	5	4	3	2	1	0
PWMMOD[1:0]		GP	PWMTYP	FBINEN	PWMDIV[2:0]		
R/W		R/W	R/W	R/W	R/W		

Address: DFH Reset value: 0000 0000b

Bit	Name	Description
5	GP	Group mode enable This bit enables the group mode. If enabled, the duty of first three pairs of PWM are decided by PWM01H and PWM01L rather than their original duty control registers. 0 = Group mode Disabled. 1 = Group mode Enabled.
2:0	PWMDIV[2:0]	PWM clock divider This field decides the pre-scale of PWM clock source. 000 = 1/1. 001 = 1/2 010 = 1/4. 011 = 1/8. 100 = 1/16. 101 = 1/32. 110 = 1/64. 111 = 1/128.

A or ACC – Accumulator (Bit-addressable)

7	6	5	4	3	2	1	0
ACC.7	ACC.6	ACC.5	ACC.4	ACC.3	ACC.2	ACC.1	ACC.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: E0H Reset value: 0000 0000b

Bit	Name	Description
7:0	ACC[7:0]	Accumulator The A or ACC register is the standard 80C51 accumulator for arithmetic operation.

ADCCON1 – ADC Control 1

7	6	5	4	3	2	1	0
OCEN	STADCPX	ADCDIV[1:0]		ETGTYP[1:0]		ADCEX	ADCEN
R/W	R/W	R/W		R/W		R/W	R/W

Address: E1H Reset value: 0000 0000b

Bit	Name	Description
6	STADCPX	External start ADC trigger pin select 0 = Assign STADC to P0.4. 1 = Assign STADC to P1.3. Note that STADC will exchange immediately once setting or clearing this bit.
5:4	ADCDIV[1:0]	ADC clock divider 00 = ADC clock source = FSYS/1. 01 = ADC clock source = FSYS/2. 10 = ADC clock source = FSYS/4. 11 = ADC clock source = FSYS/8.
3:2	ETGTYP[1:0]	External trigger type select When ADCEX (ADCCON1.1) is set, these bits select which condition triggers ADC conversion. 00 = Falling edge on PWM0/2/4 or STADC pin. 01 = Rising edge on PWM0/2/4 or STADC pin. 10 = Central point of a PWM period. 11 = End point of a PWM period. Note that the central point interrupt or the period point interrupt is only available for PWM center-aligned type.
1	ADCEX	ADC external conversion trigger select This bit select the methods of triggering an A/D conversion. 0 = A/D conversion is started only via setting ADCS bit. 1 = A/D conversion is started via setting ADCS bit or by external trigger source depending on ETGSEL[1:0] and ETGTYP[1:0]. Note that while ADCS is 1 (busy in converting), the ADC will ignore the following external trigger until ADCS is hardware cleared.
0	ADCEN	ADC enable 0 = ADC circuit off. 1 = ADC circuit on.

ADCCON2 – ADC Control 2

7	6	5	4	3	2	1	0
ADFBEN	ADCMPOP	ADCMPEN	ADCMPO	ADCAQT[2:0]			ADCDLY.8
R/W	R/W	R/W	R	R/W			R/W

Address: E2H Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7	ADFBEN	ADC compare result asserting Fault Brake enable 0 = ADC asserting Fault Brake Disabled. 1 = ADC asserting Fault Brake Enabled. Fault Brake is asserted once its compare result ADCMPO is 1. Meanwhile, PWM channels output Fault Brake data. PWMRUN (PWMCON0.7) will also be automatically cleared by hardware. The PWM output resumes when PWMRUN is set again.
6	ADCMPOP	ADC comparator output polarity 0 = ADCMPO is 1 if ADCR[11:0] is greater than or equal to ADCMP[11:0]. 1 = ADCMPO is 1 if ADCR[11:0] is less than ADCMP[11:0].
5	ADCMPE	ADC result comparator enable 0 = ADC result comparator Disabled. 1 = ADC result comparator Enabled.
4	ADCMPO	ADC comparator output value This bit is the output value of ADC result comparator based on the setting of ACMPOP. This bit updates after every A/D conversion complete.
3:1	ADCAQT	ADC acquisition time This 3-bit field decides the acquisition time for ADC sampling, following by equation below: $\text{ADC acquisition time} = \frac{4 * \text{ADCAQT} + 6}{F_{\text{ADC}}}$ The default and minimum acquisition time is 6 ADC clock cycles. Note that this field should not be changed when ADC is in converting.
0	ADCDLY.8	ADC external trigger delay counter bit 8 See ADCDLY register.

ADCDLY – ADC Trigger Delay Counter

7	6	5	4	3	2	1	0
ADCDLY[7:0]							
R/W							

Address: E3H Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCDLY[7:0]	ADC external trigger delay counter low byte This 8-bit field combined with ADCCON2.0 forms a 9-bit counter. This counter inserts a delay after detecting the external trigger. An A/D converting starts after this period of delay. $\text{External trigger delay time} = \frac{\text{ADCDLY}}{F_{\text{ADC}}}$ Note that this field is valid only when ADCEX (ADCCON1.1) is set. User should not modify ADCDLY during PWM run time if selecting PWM output as the external ADC trigger source.

C0L – Capture 0 Low Byte

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

C0L[7:0]
R/W

Address: E4H Reset value: 0000 0000b

Bit	Name	Description
7:0	C0L[7:0]	Input capture 0 result low byte The C0L register is the low byte of the 16-bit result captured by input capture 0.

C0H – Capture 0 High Byte

7	6	5	4	3	2	1	0
C0H[7:0]							
R/W							

Address: E5H Reset value: 0000 0000b

Bit	Name	Description
7:0	C0H[7:0]	Input capture 0 result high byte The C0H register is the high byte of the 16-bit result captured by input capture 0.

C1L – Capture 1 Low Byte

7	6	5	4	3	2	1	0
C1L[7:0]							
R/W							

Address: E6H Reset value: 0000 0000b

Bit	Name	Description
7:0	C1L[7:0]	Input capture 1 result low byte The C1L register is the low byte of the 16-bit result captured by input capture 1.

C1H – Capture 1 High Byte

7	6	5	4	3	2	1	0
C1H[7:0]							
R/W							

Address: E7H Reset value: 0000 0000b

Bit	Name	Description
7:0	C1H[7:0]	Input capture 1 result high byte The C1H register is the high byte of the 16-bit result captured by input capture 1.

ADCCON0 – ADC Control 0 (Bit-addressable)

7	6	5	4	3	2	1	0
ADCF	ADCS	ETGSEL1	ETGSEL0	ADCHS3	ADCHS2	ADCHS1	ADCHS0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
-----	-----	-----	-----	-----	-----	-----	-----

Address: E8H Reset value: 0000 0000b

Bit	Name	Description
7	ADCF	ADC flag This flag is set when an A/D conversion is completed. The ADC result can be read. While this flag is 1, ADC cannot start a new converting. This bit is cleared by software.
6	ADCS	A/D converting software start trigger Setting this bit 1 triggers an A/D conversion. This bit remains logic 1 during A/D converting time and is automatically cleared via hardware right after conversion complete. The meaning of writing and reading ADCS bit is different. <u>Writing:</u> 0 = No effect. 1 = Start an A/D converting. <u>Reading:</u> 0 = ADC is in idle state. 1 = ADC is busy in converting.
5:4	ETGSEL[1:0]	External trigger source select When ADCEX (ADCCON1.1) is set, these bits select which pin output triggers ADC conversion. 00 = PWM0. 01 = PWM2. 10 = PWM4 11 = STADC pin.
3:0	ADCHS[3:0]	A/D converting channel select This field selects the activating analog input source of ADC. If ADCEN is 0, all inputs are disconnected. 0000 = ADC_CH0. 0001 = ADC_CH1. 0010 = ADC_CH2. 0011 = ADC_CH3. 0100 = ADC_CH4. 0101 = ADC_CH5. 0110 = ADC_CH6. 0111 = ADC_CH7 1000 = Internal band-gap voltage. Others = Reserved.

PICON – Pin Interrupt Control

7	6	5	4	3	2	1	0
PIT67	PIT45	PIT3	PIT2	PIT1	PIT0	PIPS[1:0]	
R/W	R/W	R/W	R/W	R/W	R/W	R/W	

Address: E9H Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7	PIT67	Pin interrupt channel 6 and 7 type select This bit selects which type that pin interrupt channel 6 and 7 is triggered. 0 = Level triggered. 1 = Edge triggered.
6	PIT45	Pin interrupt channel 4 and 5 type select This bit selects which type that pin interrupt channel 4 and 5 is triggered. 0 = Level triggered. 1 = Edge triggered.
5	PIT3	Pin interrupt channel 3 type select This bit selects which type that pin interrupt channel 3 is triggered. 0 = Level triggered. 1 = Edge triggered.
4	PIT2	Pin interrupt channel 2 type select This bit selects which type that pin interrupt channel 2 is triggered. 0 = Level triggered. 1 = Edge triggered.
3	PIT1	Pin interrupt channel 1 type select This bit selects which type that pin interrupt channel 1 is triggered. 0 = Level triggered. 1 = Edge triggered.
2	PIT0	Pin interrupt channel 0 type select This bit selects which type that pin interrupt channel 0 is triggered. 0 = Level triggered. 1 = Edge triggered.
1:0	PIPS[:0]	Pin interrupt port select This field selects which port is active as the 8-channel of pin interrupt. 00 = Port 0. 01 = Port 1. 10 = Port 2. 11 = Port 3.

PINEN – Pin Interrupt Negative Polarity Enable.

7	6	5	4	3	2	1	0
PINEN7	PINEN6	PINEN5	PINEN4	PINEN3	PINEN2	PINEN1	PINEN0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: EAH Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
n	PIPENn	Pin interrupt channel n negative polarity enable This bit enables low-level/falling edge triggering pin interrupt channel n. The level or edge triggered selection depends on each control bit PITn in PICON. 0 = Low-level/falling edge detect Disabled. 1 = Low-level/falling edge detect Enabled.

PIPEN – Pin Interrupt Positive Polarity Enable.

7	6	5	4	3	2	1	0
PIPEN7	PIPEN6	PIPEN5	PIPEN4	PIPEN3	PIPEN2	PIPEN1	PIPEN0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: EBH Reset value: 0000 0000b

Bit	Name	Description
n	PIPENn	Pin interrupt channel n positive polarity enable This bit enables high-level/rising edge triggering pin interrupt channel n. The level or edge triggered selection depends on each control bit PITn in PICON. 0 = High-level/rising edge detect Disabled. 1 = High-level/rising edge detect Enabled.

PIF – Pin Interrupt Flags

7	6	5	4	3	2	1	0
PIF7	PIF6	PIF5	PIF4	PIF3	PIF2	PIF1	PIF0
R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)	R (level) R/W (edge)

Address: ECH Reset value: 0000 0000b

Bit	Name	Description
n	PIFn	Pin interrupt channel n flag If the edge trigger is selected, this flag will be set by hardware if the channel n of pin interrupt detects an enabled edge trigger. This flag should be cleared by software. If the level trigger is selected, this flag follows the inverse of the input signal's logic level on the channel n of pin interrupt. Software cannot control it.

C2L – Capture 2 Low Byte

7	6	5	4	3	2	1	0
C2L[7:0]							
R/W							

Address: EDH Reset value: 0000 0000b

Bit	Name	Description
7:0	C2L[7:0]	Input capture 2 result low byte The C2L register is the low byte of the 16-bit result captured by input capture 2.

C2H – Capture 2 High Byte

7	6	5	4	3	2	1	0
C2H[7:0]							
R/W							

Address: EEH Reset value: 0000 0000b

Bit	Name	Description
7:0	C2H[7:0]	Input capture 2 result high byte The C2H register is the high byte of the 16-bit result captured by input capture 2.

EIP – Extensive Interrupt Priority^[3]

7	6	5	4	3	2	1	0
PT2	PSPI	PFB	PWDT	PPWM	PCAP	PPI	PI2C
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: EFH Reset value: 0000 0000b

Bit	Name	Description
7	PT2	Timer 2 interrupt priority low bit
6	PSPI	SPI interrupt priority low bit
5	PFB	Fault Brake interrupt priority low bit
4	PWDT	WDT interrupt priority low bit
3	PPWM	PWM interrupt priority low bit
2	PCAP	Input capture interrupt priority low bit
1	PPI	Pin interrupt priority low bit
0	PI2C	I ² C interrupt priority low bit

Note: EIP is used in combination with the EIPH to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

B – B Register (Bit-addressable)

7	6	5	4	3	2	1	0
B.7	B.6	B.5	B.4	B.3	B.2	B.1	B.0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F0H Reset value: 0000 0000b

Bit	Name	Description
7:0	B[7:0]	B register The B register is the other accumulator of the standard 80C51 .It is used mainly for MUL and DIV instructions.

CAPCON3 – Input Capture Control 3

7	6	5	4	3	2	1	0
CAP13	CAP12	CAP11	CAP10	CAP03	CAP02	CAP01	CAP00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Name	Description
[3:0]	CAP2[3:0]	Input capture channel 0 input pin select 0000 = P1.2/IC0 0001 = P1.1/IC1 0010 = P1.0/IC2 0011 = P0.0/IC3 0100 = P0.4/IC3 0101 = P0.1/IC4 0110 = P0.3/IC5 0111 = P0.5/IC6 1000 = P1.5/IC7 others = P1.2/IC0

SPCR – Serial Peripheral Control Register

7	6	5	4	3	2	1	0
SSOE	SPIEN	LSBFE	MSTR	CPOL	CPHA	SPR1	SPR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F3H, page 0 Reset value: 0000 0000b

Bit	Name	Description
7	SSOE	Slave select output enable This bit is used in combination with the DISMODF (SPSR.3) bit to determine the feature of \overline{SS} pin as shown in 0 = \overline{SS} functions as a general purpose I/O pin. 1 = \overline{SS} automatically goes low for each transmission when selecting external Slave device and goes high during each idle state to de-select the Slave device.
6	SPIEN	SPI enable 0 = SPI function Disabled. 1 = SPI function Enabled.
5	LSBFE	LSB first enable 0 = The SPI data is transferred MSB first. 1 = The SPI data is transferred LSB first.
4	MSTR	Master mode enable This bit switches the SPI operating between Master and Slave modes. 0 = The SPI is configured as Slave mode. 1 = The SPI is configured as Master mode.
3	CPOL	SPI clock polarity select CPOL bit determines the idle state level of the SPI clock. See Figure 15.3-1 SPI Clock Formats . 0 = The SPI clock is low in idle state. 1 = The SPI clock is high in idle state.

Bit	Name	Description																																								
2	CPHA	<p>SPI clock phase select</p> <p>CPHA bit determines the data sampling edge of the SPI clock. See Figure 15.3-1 SPI Clock Formats.</p> <p>0 = The data is sampled on the first edge of the SPI clock.</p> <p>1 = The data is sampled on the second edge of the SPI clock.</p>																																								
1:0	SPR[1:0]	<p>SPI clock rate select</p> <p>These two bits select four grades of SPI clock divider. SPIS[1:0] are valid only under Master mode (MSTR = 1).					

SPSR – Serial Peripheral Status Register

7	6	5	4	3	2	1	0
SPIF	WCOL	SPIOVF	MODF	DISMODF	TXBUF	-	-
R/W	R/W	R/W	R/W	R/W	R	-	-

Address: F4H Reset value: 0000 0000b

Bit	Name	Description
7	SPIF	SPI complete flag This bit is set to logic 1 via hardware while an SPI data transfer is complete or an receiving data has been moved into the SPI read buffer. If ESPI (EIE .0) and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software. Attempting to write to SPDR is inhibited if SPIF is set.
6	WCOL	Write collision error flag This bit indicates a write collision event. Once a write collision event occurs, this bit will be set. It should be cleared via software.
5	SPIOVF	SPI overrun error flag This bit indicates an overrun event. Once an overrun event occurs, this bit will be set. If ESPI and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software.
4	MODF	Mode Fault error flag This bit indicates a Mode Fault error event. If \overline{SS} pin is configured as Mode Fault input (MSTR = 1 and DISMODF = 0) and \overline{SS} is pulled low by external devices, a Mode Fault error occurs. Instantly MODF will be set as logic 1. If ESPI and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software.
3	DISMODF	Disable Mode Fault error detection This bit is used in combination with the SSOE (SPCR.7) bit to determine the feature of \overline{SS} pin as shown in Table 15.1-1 Slave Select Pin Configurations . DISMODF is valid only in Master mode (MSTR = 1). 0 = Mode Fault detection Enabled. \overline{SS} serves as input pin for Mode Fault detection disregard of SSOE. 1 = Mode Fault detection Disabled. The feature of \overline{SS} follows SSOE bit.
2	TXBUF	SPI writer data buffer status This bit indicates the SPI transmit buffer status. 0 = SPI writer data buffer is empty 1 = SPI writer data buffer is full.

SPDR – Serial Peripheral Data Register

7	6	5	4	3	2	1	0
SPDR[7:0]							
R/W							

Address: F5H Reset value: 0000 0000b

Bit	Name	Description
7:0	SPDR[7:0]	Serial peripheral data This byte is used for transmitting or receiving data on SPI bus. A write of this byte is a write to the shift register. A read of this byte is actually a read of the read data buffer. In Master mode, a write to this register initiates transmission and reception of a byte simultaneously.

AINDIDS – ADC Channel Digital Input Disconnect

7	6	5	4	3	2	1	0
P11DIDS	P03DIDS	P04DIDS	P05DIDS	P06DIDS	P07DIDS	P30DIDS	P17DIDS
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F6H Reset value: 0000 0000b

Bit	Name	Description
n	PnnDIDS	ADC Channel digital input disable 0 = ADC channel n digital input Enabled. 1 = ADC channel n digital input Disabled. ADC channel n is read always 0.

EIPH – Extensive Interrupt Priority High^[4]

7	6	5	4	3	2	1	0
PT2H	PSPIH	PFBH	PWDTH	PPWMH	PCAPH	PPIH	PI2CH
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F7H Reset value: 0000 0000b

Bit	Name	Description
7	PT2H	Timer 2 interrupt priority high bit
6	PSPIH	SPI interrupt priority high bit
5	PFBH	Fault Brake interrupt priority high bit
4	PWDTH	WDT interrupt priority high bit
3	PPWMH	PWM interrupt priority high bit
2	PCAPH	Input capture interrupt priority high bit
1	PPIH	Pin interrupt priority high bit
0	PI2CH	I ² C interrupt priority high bit

Note: EIPH is used in combination with the EIP to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

SCON_1 – Serial Port 1 Control (bit-addressable)

7	6	5	4	3	2	1	0
SM0_1/FE_1	SM1_1	SM2_1	REN_1	TB8_1	RB8_1	TL_1	RI_1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F8H Reset value: 0000 0000b

Bit	Name	Description
7	SM0_1/ FE_1	Serial port 1 mode select <u>SMOD0_1 (T3CON.6) = 0:</u>
6	SM1_1	See Table 14.5-2 Serial Port UART1 Mode / baudrate Description for details. <u>SMOD0_1 (T3CON.6) = 1:</u> SM0_1/FE_1 bit is used as frame error (FE) status flag. It is cleared by software. 0 = Frame error (FE) did not occur. 1 = Frame error (FE) occurred and detected.
5	SM2_1	Multiprocessor communication mode enable The function of this bit is dependent on the serial port 1 mode. <u>Mode 0:</u> No effect. <u>Mode 1:</u> This bit checks valid stop bit. 0 = Reception is always valid no matter the logic level of stop bit. 1 = Reception is valid only when the received stop bit is logic 1 and the received data matches "Given" or "Broadcast" address. <u>Mode 2 or 3:</u> For multiprocessor communication. 0 = Reception is always valid no matter the logic level of the 9 th bit. 1 = Reception is valid only when the received 9 th bit is logic 1 and the received data matches "Given" or "Broadcast" address.
4	REN_1	Receiving enable 0 = Serial port 1 reception Disabled. 1 = Serial port 1 reception Enabled in Mode 1, 2, or 3. In Mode 0, reception is initiated by the condition REN_1 = 1 and RI_1 = 0.
3	TB8_1	9 th transmitted bit This bit defines the state of the 9 th transmission bit in serial port 1 Mode 2 or 3. It is not used in Mode 0 or 1.
2	RB8_1	9 th received bit The bit identifies the logic level of the 9 th received bit in serial port 1 Mode 2 or 3. In Mode 1, RB8_1 is the logic level of the received stop bit. SM2_1 bit as logic 1 has restriction for exception. RB8_1 is not used in Mode 0.

Bit	Name	Description
1	TI_1	Transmission interrupt flag This flag is set by hardware when a data frame has been transmitted by the serial port 1 after the 8 th bit in Mode 0 or the last data bit in other modes. When the serial port 1 interrupt is enabled, setting this bit causes the CPU to execute the serial port 1 interrupt service routine. This bit must be cleared manually via software.
0	RI_1	Receiving interrupt flag This flag is set via hardware when a data frame has been received by the serial port 1 after the 8 th bit in Mode 0 or after sampling the stop bit in Mode 1, 2, or 3. SM2_1 bit as logic 1 has restriction for exception. When the serial port 1 interrupt is enabled, setting this bit causes the CPU to execute to the serial port 1 interrupt service routine. This bit must be cleared manually via software.

PDTEN – PWM Dead-time Enable (TA protected)

7	6	5	4	3	2	1	0
-	-	-	PDTCNT.8	-	PDT45EN	PDT23EN	PDT01EN
-	-	-	R/W	-	R/W	R/W	R/W

Address: F9H Reset value: 0000 0000b

Bit	Name	Description
4	PDTCNT.8	PWM dead-time counter bit 8 See PDTCNT register.
2	PDT45EN	PWM0_CH4/ PWM0_CH5 pair dead-time insertion enable This bit is valid only when PWM4/5 is under complementary mode. 0 = No delay on GP4/GP5 pair signals. 1 = Insert dead-time delay on the rising edge of GP4/GP5 pair signals.
1	PDT23EN	PWM2/3 pair dead-time insertion enable This bit is valid only when PWM0_CH2/ PWM_CH3 is under complementary mode. 0 = No delay on GP2/GP3 pair signals. 1 = Insert dead-time delay on the rising edge of GP2/GP3 pair signals.
0	PDT01EN	PWM0_CH0/ PWM0_CH1 pair dead-time insertion enable This bit is valid only when PWM0/1 is under complementary mode. 0 = No delay on GP0/GP1 pair signals. 1 = Insert dead-time delay on the rising edge of GP0/GP1 pair signals.

PDTCNT – PWM Dead-time Counter (TA protected)

7	6	5	4	3	2	1	0
PDTCNT[7:0]							
R/W							

Address: FAH Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:0	PDTCNT[7:0]	<p>PWM dead-time counter low byte</p> <p>This 8-bit field combined with PDTEN.4 forms a 9-bit PWM dead-time counter PDTCNT. This counter is valid only when PWM is under complementary mode and the correspond PDTEN bit for PWM pair is set.</p> $\text{PWM dead-time} = \frac{\text{PDTCNT} + 1}{F_{\text{SYS}}}$ <p>Note that user should not modify PDTCNT during PWM run time.</p>

PMEN – PWM Mask Enable

7	6	5	4	3	2	1	0
-	-	PMEN5	PMEN4	PMEN3	PMEN2	PMEN1	PMEN0
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Name	Description
n	PMENn	<p>PWMn mask enable</p> <p>0 = PWMn signal outputs from its PWM generator.</p> <p>1 = PWMn signal is masked by PMDn.</p>

PMD – PWM Mask Data

7	6	5	4	3	2	1	0
-	-	PMD5	PMD4	PMD3	PMD2	PMD1	PMD0
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Address: FCH Reset value: 0000 0000b

Bit	Name	Description
n	PMDn	<p>PWMn mask data</p> <p>The PWMn signal outputs mask data once its corresponding PMENn is set.</p> <p>0 = PWMn signal is masked by 0.</p> <p>1 = PWMn signal is masked by 1.</p>

PORDIS – POR disable (TA protected)

7	6	5	4	3	2	1	0
PORDIS[7:0]							
W							

Address: FDH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
7:0	PORDIS[7:0]	<p>POR disable</p> <p>To first writing 5AH to the PORDIS and immediately followed by a writing of A5H will disable POR.</p>

EIP1 – Extensive Interrupt Priority 1^[5]

7	6	5	4	3	2	1	0
-	-	-	-	-	PWKT	PT3	PS_1
-	-	-	-	-	R/W	R/W	R/W

Address: FEH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
2	PWKT	WKT interrupt priority low bit
1	PT3	Timer 3 interrupt priority low bit
0	PS_1	Serial port 1 interrupt priority low bit

Note: EIP1 is used in combination with the EIPH1 to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

EIPH1 – Extensive Interrupt Priority High 1^[6]

7	6	5	4	3	2	1	0
-	-	-	-	-	PWKTH	PT3H	PSH_1
-	-	-	-	-	R/W	R/W	R/W

Address: FFH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
2	PWKTH	WKT interrupt priority high bit
1	PT3H	Timer 3 interrupt priority high bit
0	PSH_1	Serial port 1 interrupt priority high bit

Note: EIPH1 is used in combination with the EIP1 to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

8 I/O PORT STRUCTURE AND OPERATION

8.1 GPIO MODE

The MS51 has a maximum of 43 general purpose I/O pins which 40 bit-addressable general I/O pins grouped as 5 ports, P0 to P4, and 7 general I/O pins grouped as P5. Each port has its port control register (Px register). The writing and reading of a port control register have different meanings. A write to port control register sets the port output latch logic value, whereas a read gets the port pin logic state. These four modes are quasi-bidirectional (standard 8051 port structure), push-pull, input-only, and open-drain modes. Each port spends two special function registers PxM1 and PxM2 to select the I/O mode of port Px. The list below illustrates how to select the I/O mode of Px.n. Note that the default configuration of is input-only (high-impedance) after any reset.

PnM1.X ^[1]	PnM2.X ^[1]	I/O Type
0	0	Quasi-bidirectional
0	1	Push-pull
1	0	Input-only (high-impedance)
1	1	Open-drain
NOTE1: N = 0~5, x = 0~7		

Table 8.1-1 Configuration for Different I/O Modes

All I/O pins can be selected as TTL level inputs or Schmitt triggered inputs by selecting corresponding bit in PxS register. Schmitt triggered input has better glitch suppression capability. All I/O pins also have bit-controllable, slew rate select ability via software. The control registers are PxSR. By default, the slew rate is slow. If user would like to increase the I/O output speed, setting the corresponding bit in PxSR, the slew rate is selected in a faster level.

For example:

```
P0M1 |= 0x40;
P0M2 &= 0xBF;          //Set P0.6 as input only mode
```

8.2 Quasi-Bidirectional Mode

The quasi-bidirectional mode, as the standard 8051 I/O structure, can rule as both input and output. When the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low. When the pin is pulled low, it is driven strongly and able to sink a large current. In the quasi-bidirectional I/O structure, there are two pull-high transistors. Each of them serves different purposes. One of these pull-highs, called the “very weak” pull-high, is turned on whenever the port latch contains

The second pull-high is the “strong” pull-high. This pull-high is used to speed up 0-to-1 transitions on a quasi-bidirectional port pin when the port latch changes from logic 0 to logic 1. When this occurs, the strong pull-high turns on for two-CPU-clock time to pull the port pin high quickly. Then it turns off “very weak” pull-highs continue remaining the port pin high. The quasi-bidirectional port structure is shown below.

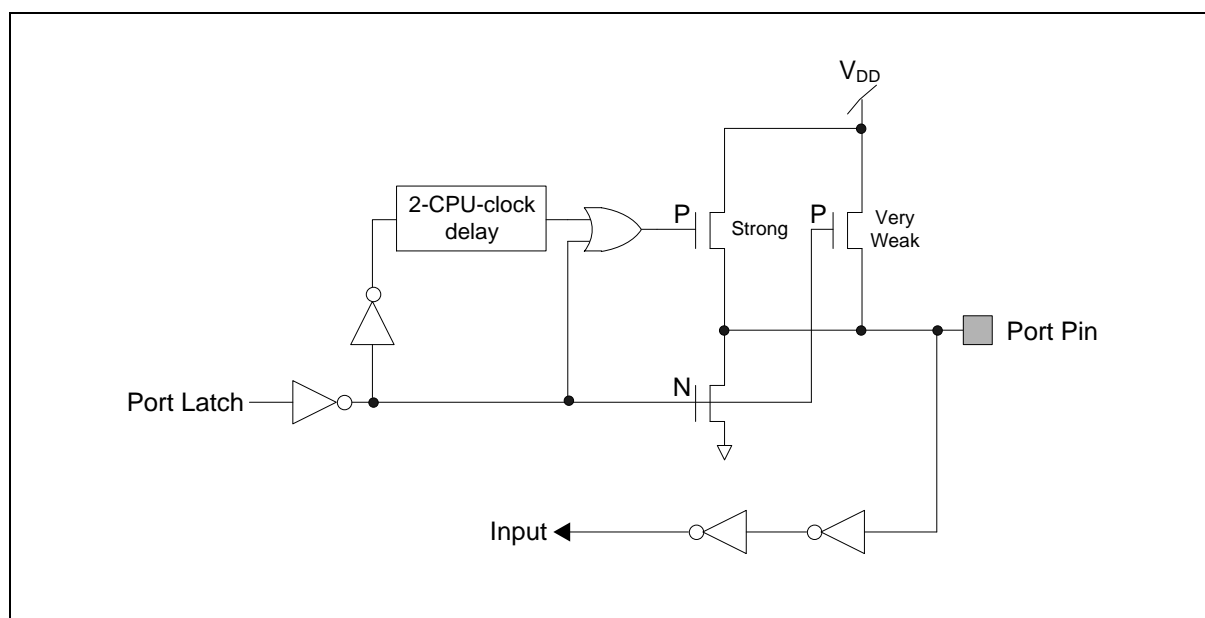

Figure 8.2-1 Quasi-Bidirectional Mode Structure

The push-pull mode has the same pull-low structure as the quasi-bidirectional mode, but provides a continuous strong pull-high when the port latch is written by logic 1. The push-pull mode is generally used as output pin when more source current is needed for an output driving.

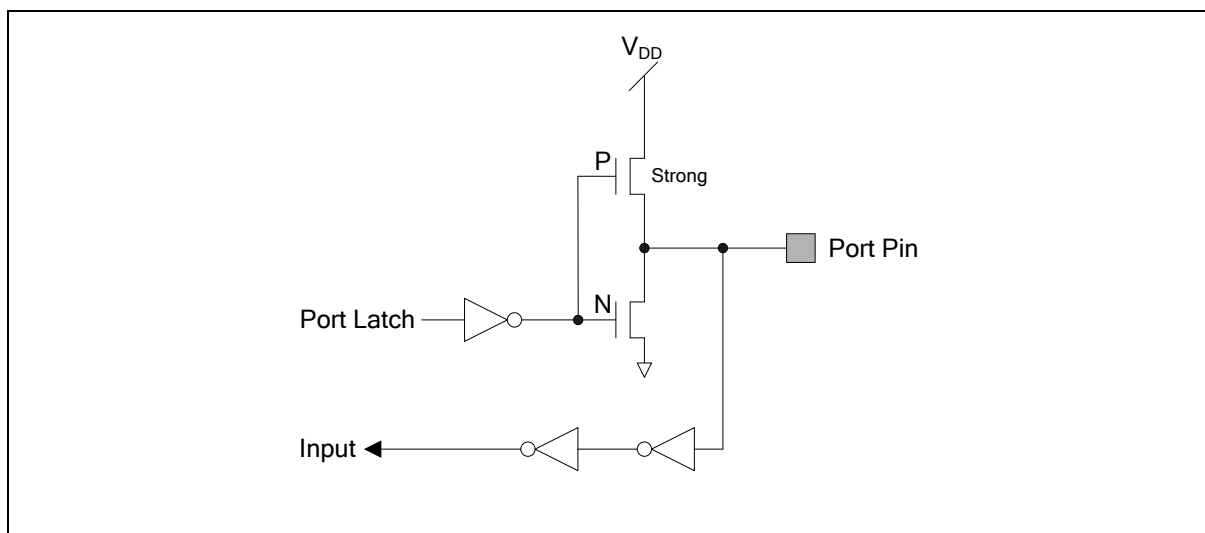

Figure 8.3-1 Push-Pull Mode Structure

8.4 Input-Only Mode

Input-only mode provides true high-impedance input path. Although a quasi-bidirectional mode I/O can also be an input pin, but it requires relative strong input source. Input-only mode also benefits to power consumption reduction for logic 0 input always consumes current from V_{DD} if in quasi-bidirectional mode. User needs to take care that an input-only mode pin should be given with a determined voltage level by external devices or resistors. A floating pin will induce leakage current especially in Power-down mode.

Figure 8.4-1 Input-Only Mode Structure

8.5 Open-Drain Mode

The open-drain mode turns off all pull-high transistors and only drives the pull-low of the port pin when the port latch is given by logic 0. If the port latch is logic 1, it behaves as if in input-only mode. To be used as an output pin generally as I^2C lines, an open-drain pin should add an external pull-high, typically a resistor tied to V_{DD} . User needs to take care that an open-drain pin with its port latch as logic 1 should be given with a determined voltage level by external devices or resistors. A floating pin will induce leakage current especially in Power-down mode.

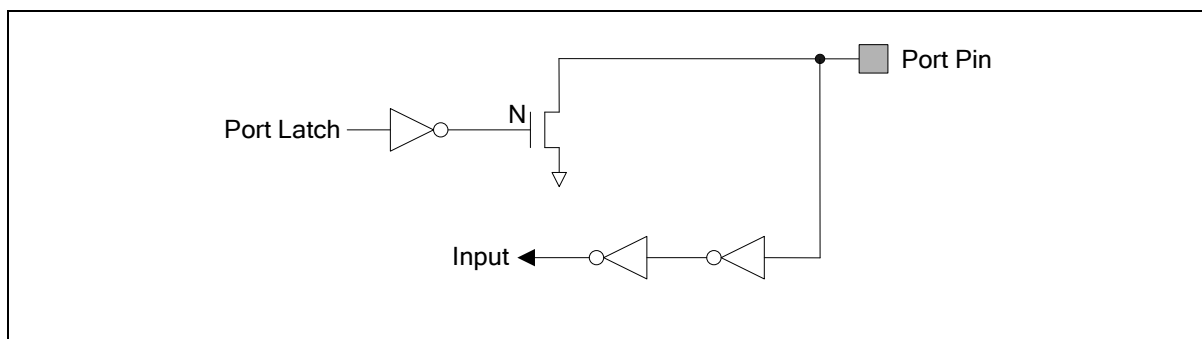

Figure 8.5-1 Open-Drain Mode Structure

8.6 Read-Modify-Write Instructions

Instructions that read a byte from SFR or internal RAM, modify it, and rewrite it back, are called “Read-Modify-Write” instructions. When the destination is an I/O port or a port bit, these instructions read the internal output latch rather than the external pin state. This kind of instructions read the port SFR value, modify it and write back to the port SFR. All “Read-Modify-Write” instructions are listed as follows.

Instruction	Description
ANL	Logical AND. (ANL direct, A and ANL direct, #data)
ORL	Logical OR. (ORL direct, A and ORL direct, #data)
XRL	Logical exclusive OR. (XRL direct, A and XRL direct, #data)
JBC	Jump if bit = 1 and clear it. (JBC bit, rel)
CPL	Complement bit. (CPL bit)
INC	Increment. (INC direct)
DEC	Decrement. (DEC direct)
DJNZ	Decrement and jump if not zero. (DJNZ direct, rel)
MOV	bit, C Move carry to bit. (MOV bit, C)
CLR	bit Clear bit. (CLR bit)
SETB	bit Set bit. (SETB bit)

The last three seem not obviously “Read-Modify-Write” instructions but actually they are. They read the entire port latch value, modify the changed bit, and then write the new value back to the port latch.

8.7 Control Registers of I/O Ports

The MS51 has a lot of I/O control registers to provide flexibility in all kinds of applications. The SFR related with I/O ports can be categorized into four groups: input and output control, output mode control, input type and sink current control, and output slew rate control. All of SFR are listed as follows.

8.7.1 Input and Output Data Control

These registers are I/O input and output data buffers. Reading gets the I/O input data. Writing forces the data output. All of these registers are bit-addressable.

P0 – Port 0 (Bit-addressable)

7	6	5	4	3	2	1	0
P0.7	P0.6	P0.5	P0.4	P0.3	P0.2	P0.1	P0.0

8.7.2 GPIO Mode Control

These registers control GPIO mode, which is configurable among four modes: input-only, quasi-bidirectional, push-pull, or open-drain. Each pin can be configured individually.

As default after reset all GPIO setting as input only mode.

PnM1.X	PnM2.X	I/O Type
0	0	Quasi-bidirectional
0	1	Push-pull
1	0	Input-only (high-impedance)
1	1	Open-drain

Bit	Name	Description
7:0	PnSR[7:0]	P0.n slew rate 0 = Pn.x normal output slew rate. 1 = Pn.x high-speed output slew rate.

9 TIMER/COUNTER 0 AND 1

Timer/Counter 0 and 1 on MS51 are two 16-bit Timers/Counters. Each of them has two 8-bit registers those form the 16-bit counting register. For Timer/Counter 0 they are TH0, the upper 8-bit register, and TL0, the lower 8-bit register. Similarly Timer/Counter 1 has two 8-bit registers, TH1 and TL1. TCON and TMOD can configure modes of Timer/Counter 0 and 1.

The Timer or Counter function is selected by the C/\bar{T} bit in TMOD. Each Timer/Counter has its own selection bit. TMOD.2 selects the function for Timer/Counter 0 and TMOD.6 selects the function for Timer/Counter 1

When configured as a “Timer”, the timer counts the system clock cycles. The timer clock is 1/12 of the system clock (F_{SYS}) for standard 8051 capability or direct the system clock for enhancement, which is selected by T0M (CKCON.3) bit for Timer 0 and T1M (CKCON.4) bit for Timer 1. In the “Counter” mode, the counter register increases on the falling edge of the external input pin T0. If the sampled value is high in one clock cycle and low in the next, a valid 1-to-0 transition is recognized on T0 or T1 pin.

The Timers 0 and 1 can be configured to automatically to toggle output whenever a timer overflow occurs. The same device pins that are used for the T0 and T1 count inputs are also used for the timer toggle outputs. This function is enabled by control bits T0OE and T1OE in the CKCON register, and apply to Timer 0 and Timer 1 respectively. The port outputs will be logic 1 prior to the first timer overflow when this mode is turned on. In order for this mode to function, the C/\bar{T} bit should be cleared selecting the system clock as the clock source for the timer.

Note that the TH0 (TH1) and TL0 (TL1) are accessed separately. It is strongly recommended that in mode 0 or 1, user should stop Timer temporarily by clearing TR0 (TR1) bit before reading from or writing to TH0 (TH1) and TL0 (TL1). The free-running reading or writing may cause unpredictable result.

Bit	Name	Description
7	TF1	Timer 1 overflow flag This bit is set when Timer 1 overflows. It is automatically cleared by hardware when the program executes the Timer 1 interrupt service routine. This bit can be set or cleared by software.
6	TR1	Timer 1 run control 0 = Timer 1 Disabled. Clearing this bit will halt Timer 1 and the current count will be preserved in TH1 and TL1. 1 = Timer 1 Enabled.

Bit	Name	Description
5	TF0	Timer 0 overflow flag This bit is set when Timer 0 overflows. It is automatically cleared via hardware when the program executes the Timer 0 interrupt service routine. This bit can be set or cleared by software.
4	TR0	Timer 0 run control 0 = Timer 0 Disabled. Clearing this bit will halt Timer 0 and the current count will be preserved in TH0 and TL0. 1 = Timer 0 Enabled.
3	IE1	External interrupt 1 edge flag If IT1 = 1 (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine. If IT1 = 0 (low level trigger), this flag follows the inverse of the $\overline{INT1}$ input signal's logic level. Software cannot control it.
2	IT1	External interrupt 1 type select This bit selects by which type that $\overline{INT1}$ is triggered. 0 = $\overline{INT1}$ is low level triggered. 1 = $\overline{INT1}$ is falling edge triggered.
1	IE0	External interrupt 0 edge flag If IT0 = 1 (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine. If IT0 = 0 (low level trigger), this flag follows the inverse of the $\overline{INT0}$ input signal's logic level. Software cannot control it.
0	IT0	External interrupt 0 type select This bit selects by which type that $\overline{INT0}$ is triggered. 0 = $\overline{INT0}$ is low level triggered. 1 = $\overline{INT0}$ is falling edge triggered.

2	T0OE	Timer 0 output enable 0 = Timer 0 output Disabled. 1 = Timer 0 output Enabled from T0 pin. Note that Timer 0 output should be enabled only when operating in its "Timer" mode.

9.1 Mode 0 (13-Bit Timer)

In Mode 0, the Timer/Counter is a 13-bit counter. The 13-bit counter consists of TH0 (TH1) and the five lower bits of TL0 (TL1). The upper three bits of TL0 (TL1) are ignored. The Timer/Counter is enabled when TR0 (TR1) is set and either GATE is 0 or $\overline{\text{INT0}}$ ($\overline{\text{INT1}}$) is 1. Gate setting as 1 allows the Timer to calculate the pulse width on external input pin $\overline{\text{INT0}}$ ($\overline{\text{INT1}}$). When the 13-bit value moves from 1FFFH to 0000H, the Timer overflow flag TF0 (TF1) is set and an interrupt occurs if enabled.

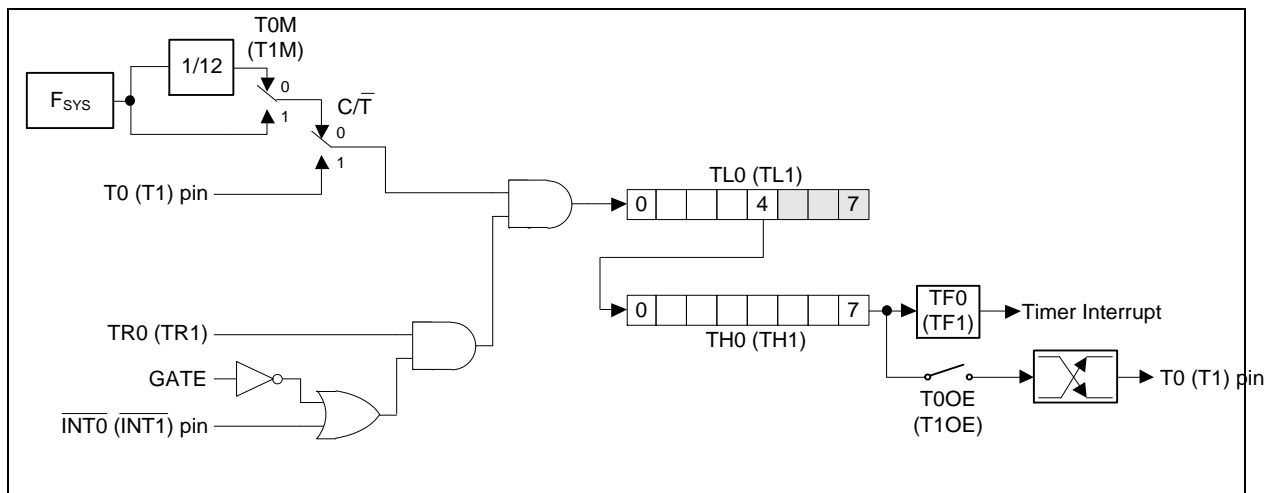

Figure 9.1-1 Timer/Counters 0 and 1 in Mode 0

9.2 Mode 1 (16-Bit Timer)

Mode 1 is similar to Mode 0 except that the counting registers are fully used as a 16-bit counter. Roll-over occurs when a count moves FFFFH to 0000H. The Timer overflow flag TF0 (TF1) of the relevant Timer/Counter is set and an interrupt will occurs if enabled.

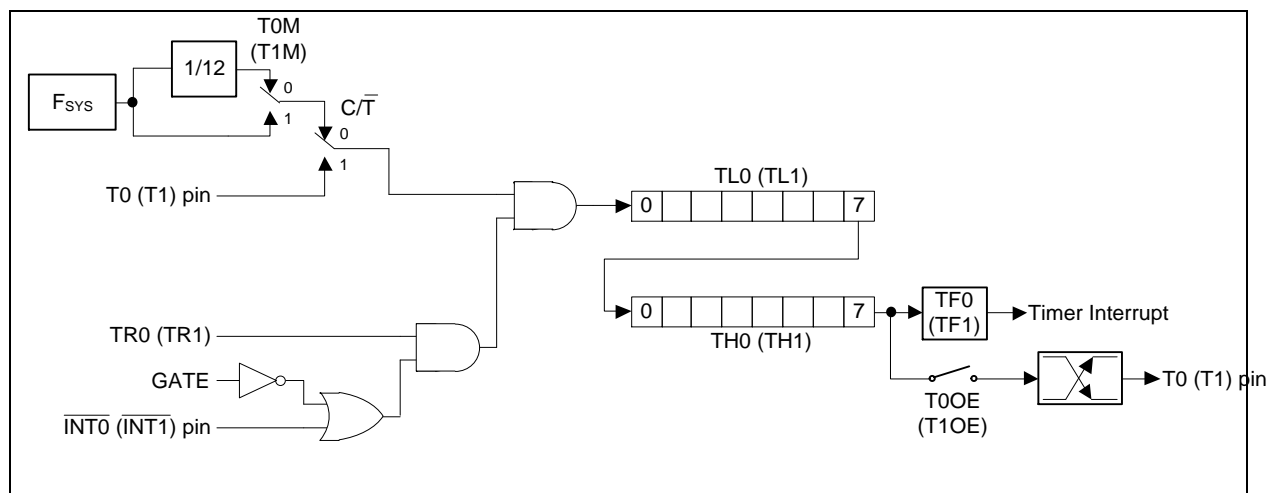

Figure 9.2-1 Timer/Counters 0 and 1 in Mode 1

9.3 Mode 2 (8-Bit Auto-Reload Timer)

In Mode 2, the Timer/Counter is in auto-reload mode. In this mode, TL0 (TL1) acts as an 8-bit count register whereas TH0 (TH1) holds the reload value. When the TL0 (TL1) register overflow, the TF0 (TF1) bit in TCON is set and TL0 (TL1) is reloaded with the contents of TH0 (TH1) and the counting process continues from here. The reload operation leaves the contents of the TH0 (TH1) register unchanged. This feature is best suitable for UART baud rate generator for it runs without continuous software intervention. Note that only Timer1 can be the baud rate source for UART. Counting is enabled by setting the TR0 (TR1) bit as 1 and proper setting of GATE and $\overline{\text{INT0}}$ ($\overline{\text{INT1}}$) pins. The functions of GATE and $\overline{\text{INT0}}$ ($\overline{\text{INT1}}$) pins are just the same as Mode 0 and 1.

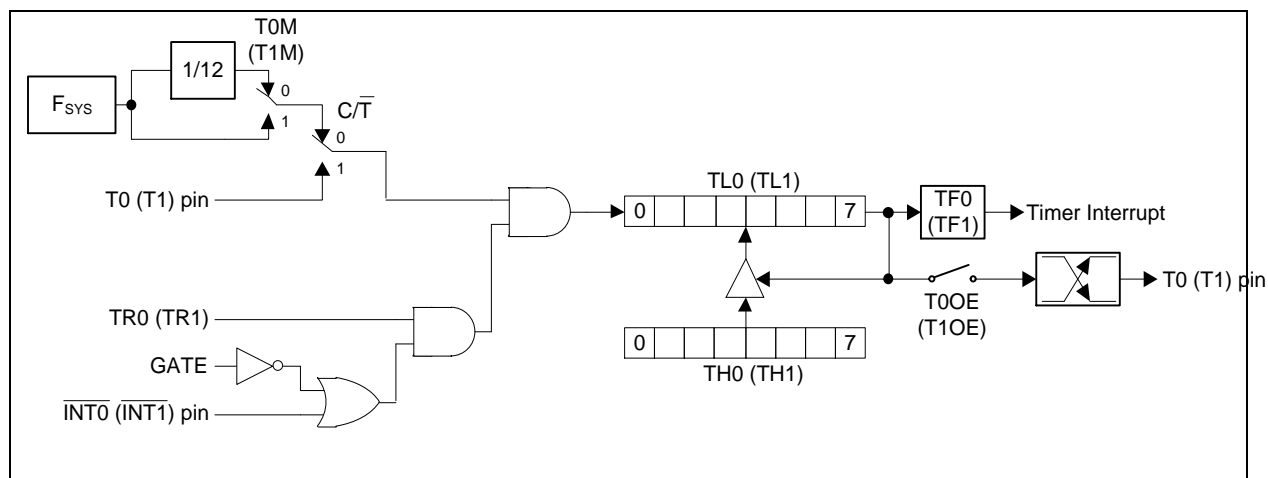

Figure 9.3-1 Timer/Counters 0 and 1 in Mode 2

9.4 Mode 3 (Two Separate 8-Bit Timers)

Mode 3 has different operating methods for Timer 0 and Timer 1. For Timer/Counter 1, Mode 3 simply freezes the counter. Timer/Counter 0, however, configures TL0 and TH0 as two separate 8 bit count

registers in this mode. TL0 uses the Timer/Counter 0 control bits C/\overline{T} , GATE, TR0, $\overline{INT0}$, and TF0. The TL0 also can be used as a 1-to-0 transition counter on pin T0 as determined by C/\overline{T} (TMOD.2). TH0 is forced as a clock cycle counter and takes over the usage of TR1 and TF1 from Timer/Counter 1. Mode 3 is used in case that an extra 8 bit timer is needed. If Timer/Counter 0 is configured in Mode 3, Timer/Counter 1 can be turned on or off by switching it out of or into its own Mode 3. It can still be used in Modes 0, 1 and 2 although its flexibility is restricted. It no longer has control over its overflow flag TF1 and the enable bit TR1. However Timer 1 can still be used as a Timer/Counter and retains the use of GATE, $\overline{INT1}$ pin and T1M. It can be used as a baud rate generator for the serial port or other application not requiring an interrupt.

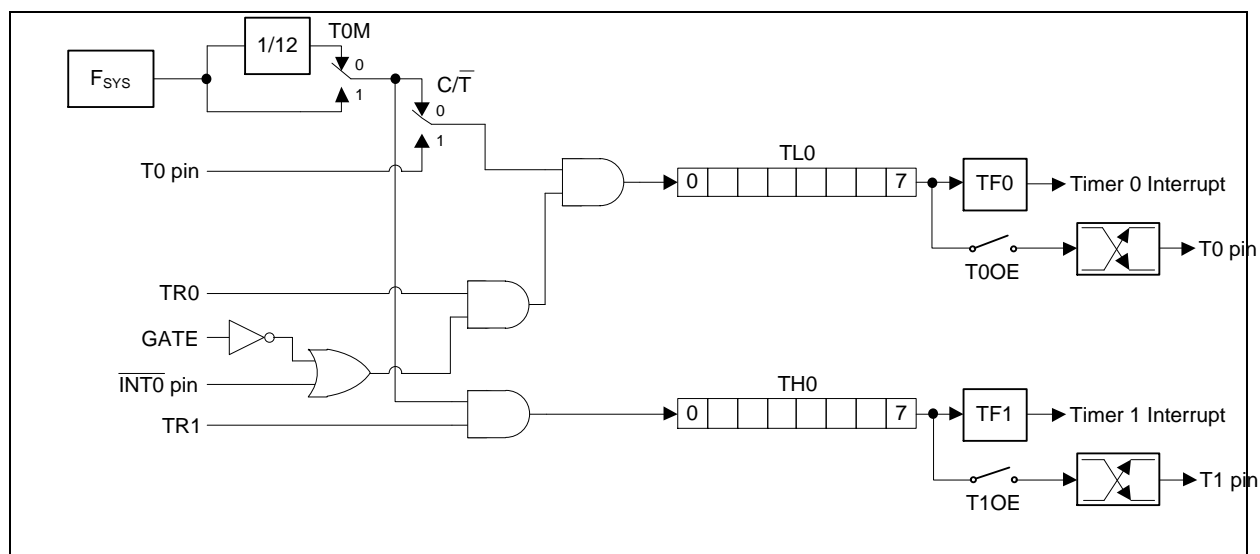

Figure 9.4-1 Timer/Counter 0 in Mode 3

10 TIMER 2 AND INPUT CAPTURE

10.1 TIMER 2 General Description

Timer 2 is a 16-bit up counter cascaded with TH2, the upper 8 bits register, and TL2, the lower 8 bit register. Equipped with RCMP2H and RCMP2L, Timer 2 can operate under compare mode and auto-reload mode selected by CM/RL2 (T2CON.0). An 3-channel input capture module makes Timer 2 detect and measure the width or period of input pulses. The results of 3 input captures are stores in C0H and C0L, C1H and C1L, C2H and C2L individually. The clock source of Timer 2 is from the system clock pre-scaled by a clock divider with 8 different scales for wide field application. The clock is enabled when TR2 (T2CON.2) is 1, and disabled when TR2 is 0. The following registers are related to Timer 2 function.

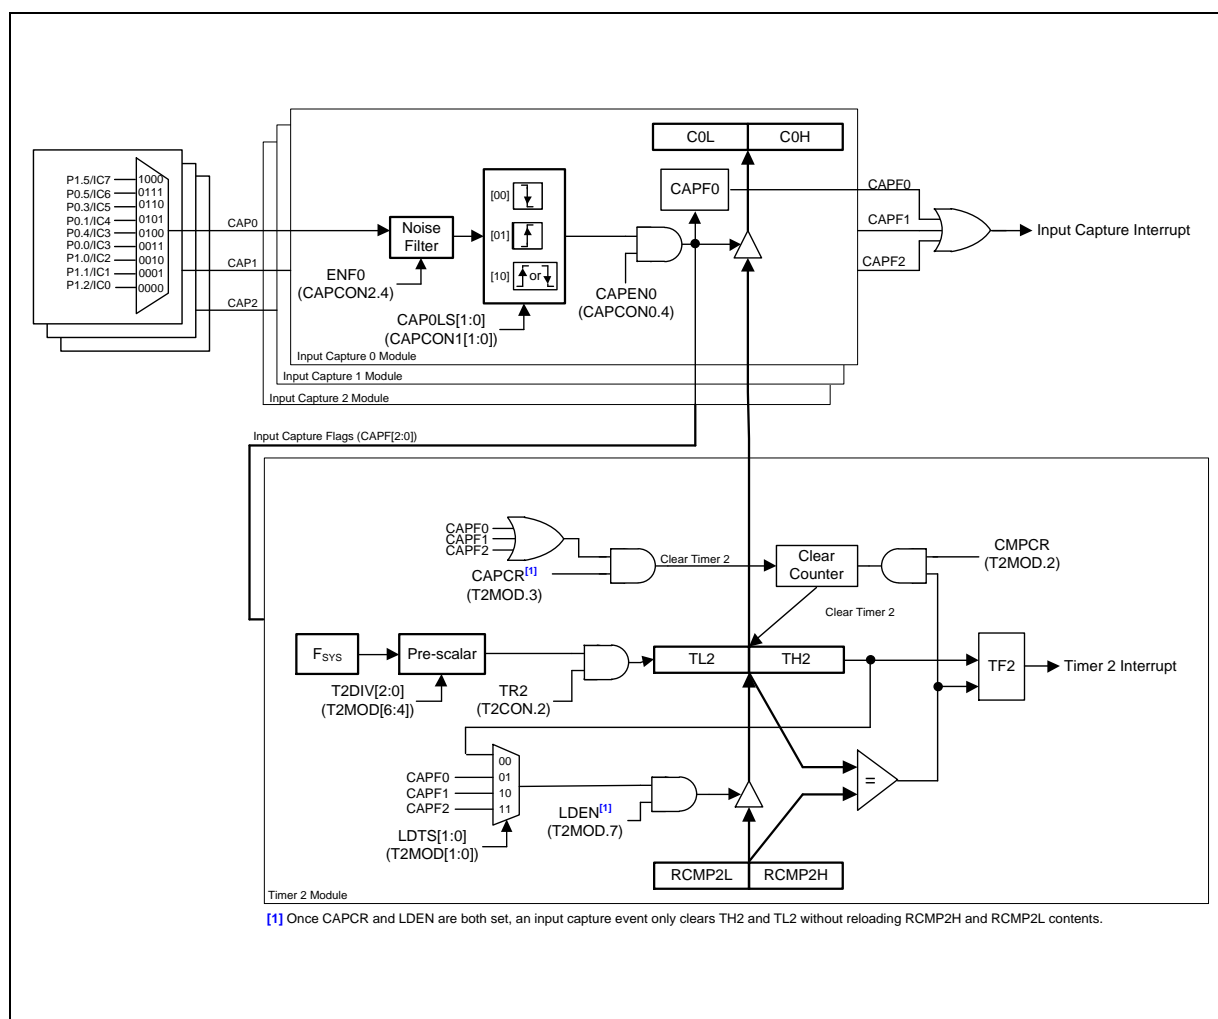

Figure 10.1-1 Timer 2 Block Diagram

T2CON – Timer 2 Control

7:0	TL2[7:0]	Timer 2 low byte The TL2 register is the low byte of the 16-bit counting register of Timer 2.

TH2 – Timer 2 High Byte

7	6	5	4	3	2	1	0
TH2[7:0]							
R/W							

Address: CDH, Page:0 Reset value: 0000 0000b

Bit	Name	Description
7:0	TH2[7:0]	Timer 2 high byte The TH2 register is the high byte of the 16-bit counting register of Timer 2.

Note that the TH2 and TL2 are accessed separately. It is strongly recommended that user stops Timer 2 temporally by clearing TR2 bit before reading from or writing to TH2 and TL2. The free-running reading or writing may cause unpredictable result.

10.2 Auto-Reload Mode

The Timer 2 is configured as auto-reload mode by clearing $\overline{CM/RL2}$. In this mode RCMP2H and RCMP2L registers store the reload value. The contents in RCMP2H and RCMP2L transfer into TH2 and TL2 once the auto-reload event occurs if setting LDEN bit. The event can be the Timer 2 overflow or one of the triggering event on any of enabled input capture channel depending on the LDTS[1:0] (T2MOD[1:0]) selection. Note that once CAPCR (T2MOD.3) is set, an input capture event only clears TH2 and TL2 without reloading RCMP2H and RCMP2L contents.

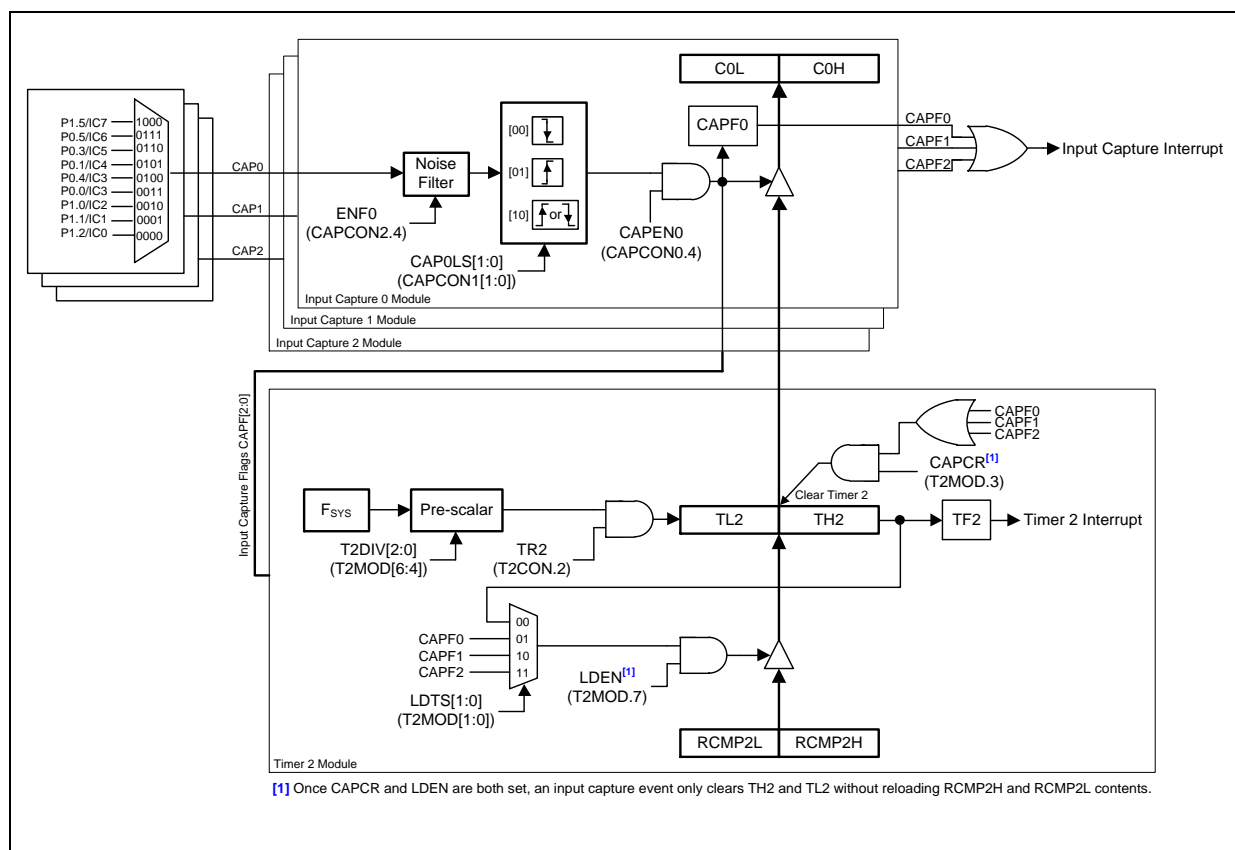

Figure 10.2-1 Timer 2 Auto-Reload Mode and Input Capture Module Functional Block Diagram

10.3 Compare Mode

Timer 2 can also be configured as the compare mode by setting $CM/\overline{RL2}$. In this mode RCMP2H and RCMP2L registers serve as the compare value registers. As Timer 2 up counting, TH2 and TL2 match RCMP2H and RCMP2L, TF2 (T2CON.7) will be set by hardware to indicate a compare match event.

Setting CMPCR (T2MOD.2) makes the hardware to clear Timer 2 counter as 0000H automatically after a compare match has occurred.

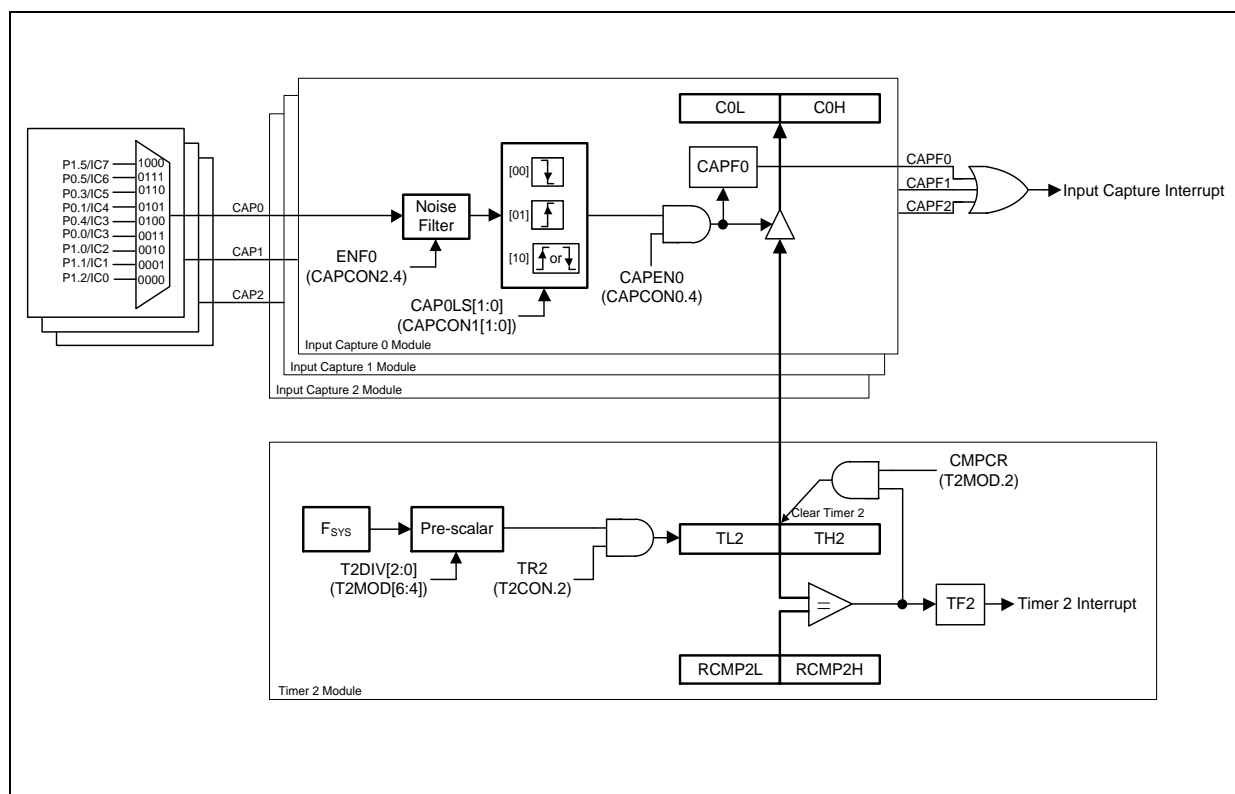

Figure 10.3-1 Timer 2 Compare Mode and Input Capture Module Functional Block Diagram

10.4 Input Capture Module

The input capture module along with Timer 2 implements the input capture function. The input capture module is configured through CAPCON0~2 registers. The input capture module supports 3-channel inputs (CAP0, CAP1, and CAP2). Each input channel consists its own noise filter, which is enabled via setting ENF0~2 (CAPCON2[6:4]). It filters input glitches smaller than four system clock cycles. Input capture channels has their own independent edge detector but share the unique Timer 2. Each trigger edge detector is selected individually by setting corresponding bits in CAPCON1. It supports positive edge capture, negative edge capture, or any edge capture. Each input capture channel has to set its own enabling bit CAPEN0~2 (CAPCON0[6:4]) before use.

While input capture channel is enabled and the selected edge trigger occurs, the content of the free running Timer 2 counter, TH2 and TL2, will be captured, transferred, and stored into the capture registers CnH and CnL. The edge triggering also causes CAPFn (CAPCON0.n) set by hardware. The interrupt will also generate if the ECAP (EIE0.2) and EA bit are both set. For three input capture flags share the same interrupt vector, user should check CAPFn to confirm which channel comes the input capture edge. These flags should be cleared by software.

The bit CAPCR (CAPCON2.3) benefits the implement of period calculation. Setting CAPCR makes the hardware clear Timer 2 as 0000H automatically after the value of TH2 and TL2 have been captured after an input capture edge event occurs. It eliminates the routine software overhead of writing 16-bit counter or an arithmetic subtraction.

11 TIMER 3

Timer 3 is implemented simply as a 16-bit auto-reload, up-counting timer. The user can select the pre-scale with T3PS[2:0] (T3CON[2:0]) and fill the reload value into RH3 and RL3 registers to determine its overflow rate. User then can set TR3 (T3CON.3) to start counting. When the counter rolls over FFFFH, TF3 (T3CON.4) is set as 1 and a reload is generated and causes the contents of the RH3 and RL3 registers to be reloaded into the internal 16-bit counter. If ET3 (EIE1.1) is set as 1, Timer 3 interrupt service routine will be served. TF3 is auto-cleared by hardware after entering its interrupt service routine.

Timer 3 can also be the baud rate clock source of both UARTs. For details, please see [Section 14.5“Baud Rate”](#).

12 WATCHDOG TIMER (WDT)

The MS51 provides one Watchdog Timer (WDT). It can be configured as a time-out reset timer to reset whole device. Once the device runs in an abnormal status or hangs up by outward interference, a WDT reset recover the system. It provides a system monitor, which improves the reliability of the system. Therefore, WDT is especially useful for system that is susceptible to noise, power glitches, or electrostatic discharge. The WDT also can be configured as a general purpose timer, of which the periodic interrupt serves as an event timer or a durational system supervisor in a monitoring system, which is able to operate during Idle or Power-down mode. WDTEN[3:0] (CONFIG4[7:4]) initialize the WDT to operate as a time-out reset timer or a general purpose timer.

CONFIG4

7	6	5	4	3	2	1	0
WDTEN[3:0]				-	-	-	-
R/W				-	-	-	-

Factory default value: 1111 1111b

Bit	Name	Description
7:4	WDTEN[3:0]	WDT enable This field configures the WDT behavior after MCU execution. 1111 = WDT is Disabled. WDT can be used as a general purpose timer via software control. 0101 = WDT is Enabled as a time-out reset timer and it stops running during Idle or Power-down mode. Others = WDT is Enabled as a time-out reset timer and it keeps running during Idle or Power-down mode.

The WDT is implemented with a set of divider that divides the low-speed internal oscillator clock nominal 10kHz. The divider output is selectable and determines the time-out interval. When the time-out interval is fulfilled, it will wake the system up from Idle or Power-down mode and an interrupt event will occur if WDT interrupt is enabled. If WDT is initialized as a time-out reset timer, a system reset will occur after a period of delay if without any software action.

WDCON – Watchdog Timer Control (TA protected)

7	6	5	4	3	2	1	0
WDTR	WDCLR	WDTF	WIDPD	WDTRF	WDPS[2:0]		
R/W	R/W	R/W	R/W	R/W	R/W		

Address: AAH, Page 0 Reset value: POR: 0000 0111b / WDT: 0000 1UUUb / Others: 0000 UUUUb

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7	WDTR	WDT run This bit is valid only when control bits in WDTE[3:0] (CONFIG4[7:4]) are all 1. At this time, WDT works as a general purpose timer. 0 = WDT Disabled. 1 = WDT Enabled. The WDT counter starts running.
6	WDCLR	WDT clear Setting this bit will reset the WDT count to 00H. It puts the counter in a known state and prohibit the system from unpredictable reset. The meaning of writing and reading WDCLR bit is different. <u>Writing:</u> 0 = No effect. 1 = Clearing WDT counter. <u>Reading:</u> 0 = WDT counter is completely cleared. 1 = WDT counter is not yet cleared.
5	WDTF	WDT time-out flag This bit indicates an overflow of WDT counter. This flag should be cleared by software.
4	WDPD	WDT running in Idle or Power-down mode This bit is valid only when control bits in WDTE[3:0] (CONFIG4[7:4]) are all 1. It decides whether WDT runs in Idle or Power-down mode when WDT works as a general purpose timer. 0 = WDT stops running during Idle or Power-down mode. 1 = WDT keeps running during Idle or Power-down mode.
3	WDTRF	WDT reset flag When the CPU is reset by WDT time-out event, this bit will be set via hardware. This flag is recommended to be cleared via software after reset.
2:0	WDPS[2:0]	WDT clock pre-scalar select These bits determine the pre-scale of WDT clock from 1/1 through 1/256. See Table 10.4-1 . The default is the maximum pre-scale value.

Note:

1. WDTRF will be cleared after power-on reset, be set after WDT reset, and remains unchanged after any other resets.
2. WDPS[2:0] are all set after power-on reset and keep unchanged after any reset other than power-on reset.

The Watchdog time-out interval is determined by the formula $\frac{1}{F_{LIRC} \times \text{clockdividerscalar}} \times 64$, where

F_{LIRC} is the frequency of internal 10 kHz oscillator. The following table shows an example of the Watchdog time-out interval with different pre-scales.

WDPS.2	WDPS.1	WDPS.0	Clock Divider Scale	WDT Time-Out Timing ^[1]
0	0	0	1/1	6.40 ms
0	0	1	1/4	25.60 ms

WDPS.2	WDPS.1	WDPS.0	Clock Divider Scale	WDT Time-Out Timing ^[1]
0	1	0	1/8	51.20 ms
0	1	1	1/16	102.40 ms
1	0	0	1/32	204.80 ms
1	0	1	1/64	409.60 ms
1	1	0	1/128	819.20 ms
1	1	1	1/256	1.638 s

Note: This is an approximate value since the deviation of LIRC.

Table 10.4-1 Watchdog Timer-out Interval Under Different Pre-scalars

Since the limitation of the maxima vaule of WDT timer delay. To up MS51 from idle mode or power down mode suggest use WKT function see Chapter 13 SELF WAKE-UP TIMER (WKT).

12.1 Time-Out Reset Timer

When the CONFIG bits WDTEN[3:0] (CONFIG4[7:4]) is not FH, the WDT is initialized as a time-out reset timer. If WDTEN[3:0] is not 5H, the WDT is allowed to continue running after the system enters Idle or Power-down mode. Note that when WDT is initialized as a time-out reset timer, WDTR and WIDPD has no function.

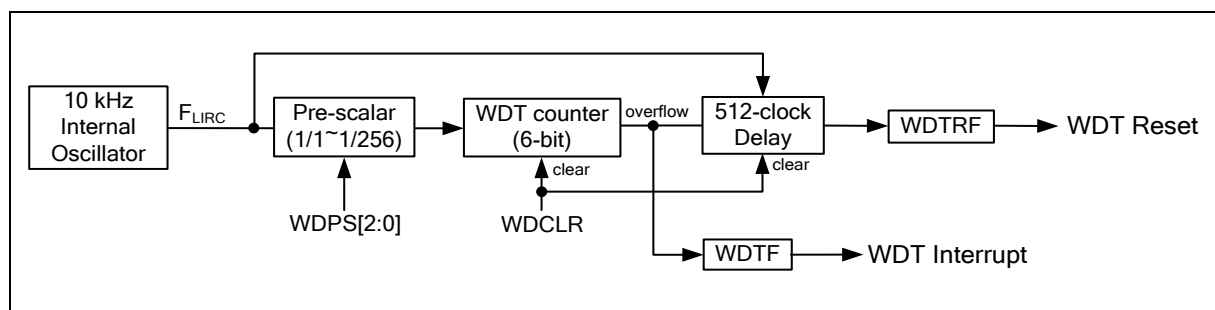

Figure 12.1-1 WDT as A Time-Out Reset Timer

After the device is powered and it starts to execute software code, the WDT starts counting simultaneously. The time-out interval is selected by the three bits WDPS[2:0] (WDCON[2:0]). When the selected time-out occurs, the WDT will set the interrupt flag WDTF (WDCON.5). If the WDT interrupt enable bit EWDT (EIE0.4) and global interrupt enable EA are both set, the WDT interrupt routine will be executed. Meanwhile, an additional 512 clocks of the low-speed internal oscillator delays to expect a counter clearing by setting WDCLR to avoid the system reset by WDT if the device operates normally. If no counter reset by writing 1 to WDCLR during this 512-clock period, a WDT reset will happen. Setting WDCLR bit is used to clear the counter of the WDT. This bit is self-cleared

for user monitoring it. Once a reset due to WDT occurs, the WDT reset flag WDTRF (WDCON.3) will be set. This bit keeps unchanged after any reset other than a power-on reset. User may clear WDTRF via software. Note that all bits in WDCON require timed access writing.

The main application of the WDT with time-out reset enabling is for the system monitor. This is important in real-time control applications. In case of some power glitches or electro-magnetic interference, CPU may begin to execute erroneous codes and operate in an unpredictable state. If this is left unchecked the entire system may crash. Using the WDT during software development requires user to select proper “Feeding Dog” time by clearing the WDT counter. By inserting the instruction of setting WDCLR, it allows the code to run without any WDT reset. However If any erroneous code executes by any interference, the instructions to clear the WDT counter will not be executed at the required instants. Thus the WDT reset will occur to reset the system state from an erroneously executing condition and recover the system.

12.2 General Purpose Timer

There is another application of the WDT, which is used as a simple, long period timer. When the CONFIG bits WDTE[3:0] (CONFIG4[7:4]) is FH, the WDT is initialized as a general purpose timer. In this mode, WDTR and WIDPD are fully accessed via software.

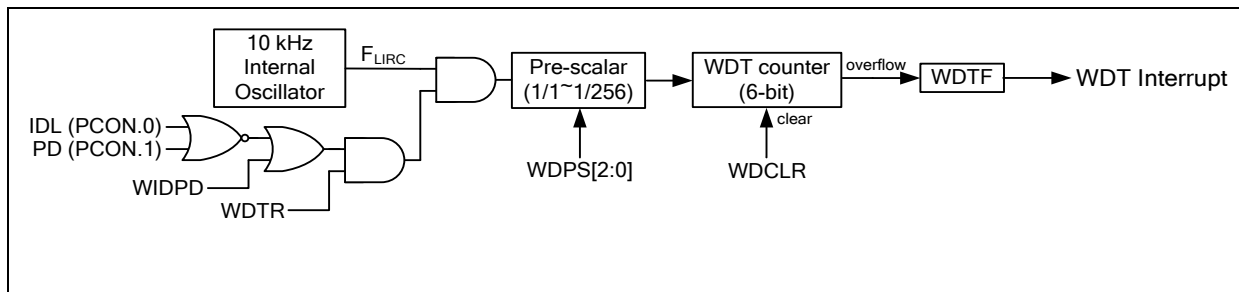

Figure 12.2-1 Watchdog Timer Block Diagram

The WDT starts running by setting WDTR as 1 and halts by clearing WDTR as 0. The WDTRF flag will be set while the WDT completes the selected time interval. The software polls the WDTRF flag to detect a time-out. An interrupt will occur if the individual interrupt EWDT (EIE0.4) and global interrupt enable EA is set. WDT will continue counting. User should clear WDTRF and wait for the next overflow by polling WDTRF flag or waiting for the interrupt occurrence.

In some application of low power consumption, the CPU usually stays in Idle mode when nothing needs to be served to save power consumption. After a while the CPU will be woken up to check if anything needs to be served at an interval of programmed period implemented by Timer 0~3. However, the current consumption of Idle mode still keeps at a “mA” level. To further reducing the current consumption to “uA” level, the CPU should stay in Power-down mode when nothing needs to be served, and has the ability of waking up at a programmable interval. The MS51 is equipped with

this useful function by WDT waking up. It provides a very low power internal oscillator 10 kHz as the clock source of the WDT. It is also able to count under Power-down mode and wake CPU up. The demo code to accomplish this feature is shown below.

13 SELF WAKE-UP TIMER (WKT)

The MS51 has a dedicated Self Wake-up Timer (WKT), which serves for a periodic wake-up timer in low power mode or for general purpose timer. WKT remains counting in Idle or Power-down mode. When WKT is being used as a wake-up timer, a start of WKT can occur just prior to entering a power management mode. WKT has one clock source, internal 10 kHz. Note that the system clock frequency must be twice over WKT clock. If WKT starts counting, the selected clock source will remain active once the device enters Idle or Power-down mode. Note that the selected clock source of WKT will not automatically enabled along with WKT configuration. User should manually enable the selected clock source and waiting for stability to ensure a proper operation.

The WKT is implemented simply as a 8-bit auto-reload, up-counting timer with pre-scale 1/1 to 1/2048 selected by WKPS[2:0] (WKCON[2:0]). User fills the reload value into RWK register to determine its overflow rate. The WKTR (WKCON.3) can be set to start counting. When the counter rolls over FFH, WKTF (WKCON.4) is set as 1 and a reload is generated and causes the contents of the RWK register to be reloaded into the internal 8-bit counter. If EWKT (EIE1.2) is set as 1, WKT interrupt service routine will be served.

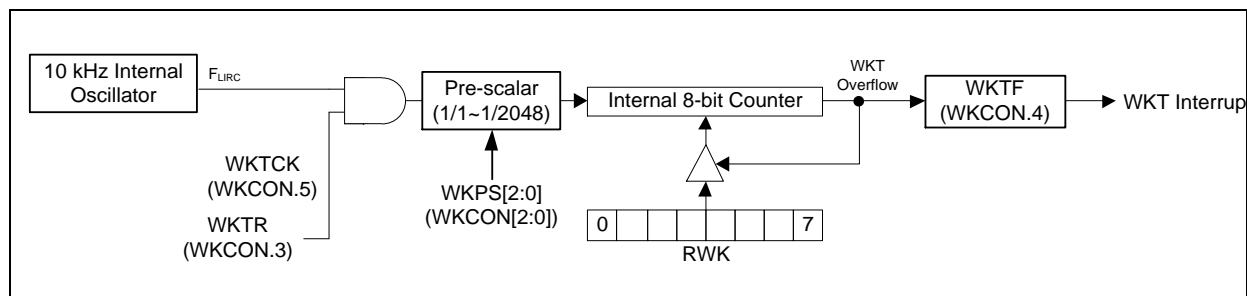

Figure 12.2-1 Self Wake-Up Timer Block Diagram

WKCON – Self Wake-up Timer Control

7	6	5	4	3	2	1	0
-	-	-	WKTF	WKTR	WKPS[2:0]		
-	-	-	R/W	R/W	R/W		

Address: 8FH, all pages Reset value: 0000 0000b

Bit	Name	Description
7:5	-	Reserved
4	WKTF	WKT overflow flag This bit is set when WKT overflows. If the WKT interrupt and the global interrupt are enabled, setting this bit will make CPU execute WKT interrupt service routine. This bit is not automatically cleared via hardware and should be cleared via software.

Bit	Name	Description
3	WKTR	WKT run control 0 = WKT is halted. 1 = WKT starts running. Note that the reload register RWK can only be written when WKT is halted (WKTR bit is 0). If WKT is written while WKTR is 1, result is unpredictable.
2:0	WKPS[2:0]	WKT pre-scalar These bits determine the pre-scale of WKT clock. 000 = 1/1. 001 = 1/4. 010 = 1/16. 011 = 1/64. 100 = 1/256. 101 = 1/512. 110 = 1/1024. 111 = 1/2048.

RWK – Self Wake-up Timer Reload Byte

7	6	5	4	3	2	1	0
RWK[7:0]							
R/W							

Address: 86H, all pages Reset value: 0000 0000b

Bit	Name	Description
7:0	RWK[7:0]	WKT reload byte It holds the 8-bit reload value of WKT. Note that RWK should not be FFH if the pre-scale is 1/1 for implement limitation.

14 SERIAL PORT (UART0 & UART1)

The MS51 includes two enhanced full duplex serial ports enhanced with automatic address recognition and framing error detection. As control bits of these two serial ports are implemented the same. Generally speaking, in the following contents, there will not be any reference to serial port 1, but only to serial port 0.

Each serial port supports one synchronous communication mode, Mode 0, and three modes of full duplex UART (Universal Asynchronous Receiver and Transmitter), Mode 1, 2, and 3. This means it can transmit and receive simultaneously. The serial port is also receiving-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the register. The receiving and transmitting registers are both accessed at SBUF. Writing to SBUF loads the transmitting register, and reading SBUF accesses a physically separate receiving register. There are four operation modes in serial port. In all four modes, transmission initiates by any instruction that uses SBUF as a destination register.

14.1 Mode 0

Mode 0 provides synchronous communication with external devices. Serial data centers and exits through RXD pin. TXD outputs the shift clocks. 8-bit frame of data are transmitted or received. Mode 0 therefore provides half-duplex communication because the transmitting or receiving data is via the same data line RXD. The baud rate is enhanced to be selected as $F_{SYS}/12$ if SM2 (SCON.5) is 0 or as $F_{SYS}/2$ if SM2 is 1. Note that whenever transmitting or receiving, the serial clock is always generated by the MCU. Thus any device on the serial port in Mode 0 should accept the MCU as the master. Figure 14.1-1 shows the associated timing of the serial port in Mode 0.

Figure 14.1-1 Serial Port Mode 0 Timing Diagram

As shown there is one bi-directional data line (RXD) and one shift clock line (TXD). The shift clocks are used to shift data in or out of the serial port controller bit by bit for a serial communication. Data bits enter or emit LSB first. The band rate is equal to the shift clock frequency.

Transmission is initiated by any instruction writes to SBUF. The control block will then shift out the clocks and begin to transfer data until all 8 bits are complete. Then the transmitted flag TI (SCON.1) will be set 1 to indicate one byte transmitting complete.

Reception is initiated by the condition REN (SCON.4) = 1 and RI (SCON.0) = 0. This condition tells the serial port controller that there is data to be shifted in. This process will continue until 8 bits have been received. Then the received flag RI will be set as 1. User can clear RI to triggering the next byte reception.

14.2 Mode 1

Mode 1 supports asynchronous, full duplex serial communication. The asynchronous mode is commonly used for communication with PCs, modems or other similar interfaces. In Mode 1, 10 bits are transmitted through TXD or received through RXD including a start bit (logic 0), 8 data bits (LSB first) and a stop bit (logic 1). The baud rate is determined by the Timer 1. SMOD (PCON.7) setting 1 makes the baud rate double. [Figure 14.2-1](#) shows the associated timings of the serial port in Mode 1 for transmitting and receiving.

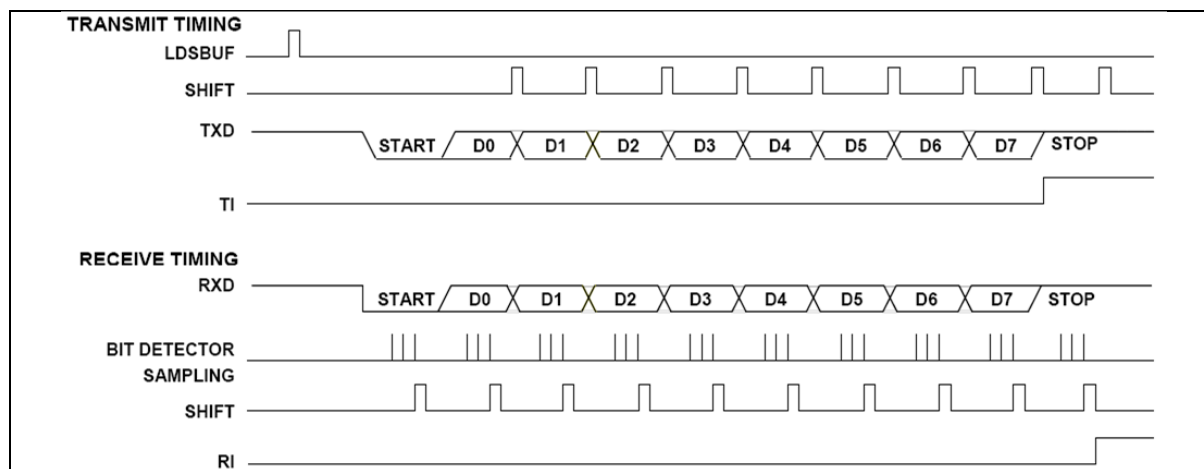

Figure 14.2-1 Serial Port Mode 1 Timing Diagram

Transmission is initiated by any writing instructions to SBUF. Transmission takes place on TXD pin. First the start bit comes out, the 8-bit data follows to be shifted out and then ends with a stop bit. After the stop bit appears, TI (SCON.1) will be set to indicate one byte transmission complete. All bits are shifted out depending on the rate determined by the baud rate generator.

Once the baud rate generator is activated and REN (SCON.4) is 1, the reception can begin at any time. Reception is initiated by a detected 1-to-0 transition at RXD. Data will be sampled and shifted in

at the selected baud rate. In the midst of the stop bit, certain conditions should be met to load SBUF with the received data:

1. RI (SCON.0) = 0, and
2. Either SM2 (SCON.5) = 0, or the received stop bit = 1 while SM2 = 1 and the received data matches “Given” or “Broadcast” address. (For enhancement function, see Section 14.7 “Multiprocessor Communication” and Section 14.8 “Automatic Address Recognition”.)

If these conditions are met, then the SBUF will be loaded with the received data, the RB8 (SCON.2) with stop bit, and RI will be set. If these conditions fail, there will be no data loaded and RI will remain 0. After above receiving progress, the serial control will look forward another 1-to-0 transition on RXD pin to start next data reception.

14.3 Mode 2

Mode 2 supports asynchronous, full duplex serial communication. Different from Mode1, there are 11 bits to be transmitted or received. They are a start bit (logic 0), 8 data bits (LSB first), a programmable 9th bit TB8 or RB8 bit and a stop bit (logic 1). The most common use of 9th bit is to put the parity bit in it or to label address or data frame for multiprocessor communication. The baud rate is fixed as 1/32 or 1/64 the system clock frequency depending on SMOD (PCON.7) bit. [Figure 14.3-1](#) shows the associated timings of the serial port in Mode 2 for transmitting and receiving.

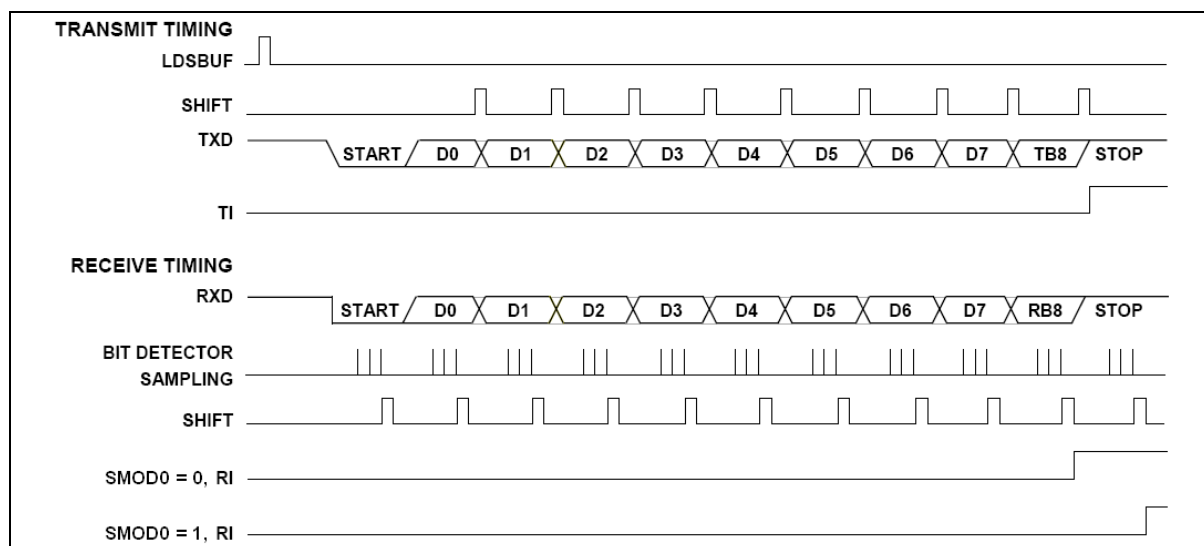

Figure 14.3-1 Serial Port Mode 2 and 3 Timing Diagram

Transmission is initiated by any writing instructions to SBUF. Transmission takes place on TXD pin. First the start bit comes out, the 8-bit data and bit TB8 (SCON.3) follows to be shifted out and then ends with a stop bit. After the stop bit appears, TI will be set to indicate the transmission complete.

While REN is set, the reception is allowed at any time. A falling edge of a start bit on RXD will initiate the reception progress. Data will be sampled and shifted in at the selected baud rate. In the midst of the stop bit, certain conditions should be met to load SBUF with the received data:

1. RI (SCON.0) = 0, and
2. Either SM2 (SCON.5) = 0, or the received 9th bit = 1 while SM2 = 1 and the received data matches “Given” or “Broadcast” address. (For enhancement function, see Section 14.7 “Multiprocessor Communication” and Section 14.8 “Automatic Address Recognition”.)

If these conditions are met, the SBUF will be loaded with the received data, the RB8(SCON.2) with the received 9th bit and RI will be set. If these conditions fail, there will be no data loaded and RI will remain 0. After above receiving progress, the serial control will look forward another 1-to-0 transition on RXD pin to start next data reception.

14.4 Mode 3

Mode 3 has the same operation as Mode 2, except its baud rate clock source uses Timer 1 overflows as its baud rate clocks. See [Figure 14.3-1](#) for timing diagram of Mode 3. It has no difference from Mode 2.

14.5 Baud Rate

The baud rate source and speed for different modes of serial port is quite different from one another. All cases are listed in Table 14.5-1 Serial Port UART0 Mode / baudrate Description. The user should calculate the baud rate according to their system configuration.

In Mode 1 or 3, the baud rate clock source of UART0 can be selected from Timer 1 or Timer 3. User can select the baud rate clock source by BRCK (T3CON.5). For UART1, its baud rate clock comes only from Timer 3 as its unique clock source.

When using Timer 1 as the baud rate clock source, note that the Timer 1 interrupt should be disabled. Timer 1 itself can be configured for either “Timer” or “Counter” operation. It can be in any of its three running modes. However, in the most typical applications, it is configured for “Timer” operation, in the auto-reload mode (Mode 2). If using Timer 3 as the baud rate generator, its interrupt should also be disabled.

Following shows all UART mode and baudrate formula:

Mode	Frame Bits	SM0 / SM1 (SCON[7:6])	SM2 (SCON[5])	SMOD (PCON[7])	Baud Rate	
0	8	00	0	-	FSYS divided by 12	
			1		FSYS divided by 2	
1	10	01	-	0	Time1 TM1 CKCON[3] = 0	$\frac{1}{32} \times \frac{F_{SYS}}{12 \times (256 - TH1)}$
					Time1 TM1 CKCON[3] = 1	$\frac{1}{32} \times \frac{F_{SYS}}{(256 - TH1)}$
					Timer 3	$\frac{1}{32} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
				1	Time1 TM1 CKCON[3] = 0	$\frac{1}{16} \times \frac{F_{SYS}}{12 \times (256 - TH1)}$
					Time1 TM1 CKCON[3] = 1	$\frac{1}{16} \times \frac{F_{SYS}}{(256 - TH1)}$
					Timer 3	$\frac{1}{16} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
2	11	10	-	0	FSYS divided by 64	
				1	FSYS divided by 32	
3	11	11	-	0	Time 1 ^[1] TM1 CKCON[3] = 0	$\frac{1}{32} \times \frac{F_{SYS}}{12 \times (256 - TH1)}$
					Time 1 ^[1] TM1 CKCON[3] = 1	$\frac{1}{32} \times \frac{F_{SYS}}{(256 - TH1)}$
					Timer 3	$\frac{1}{32} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
				1	Time1 ^[1] TM1 CKCON[3] = 0	$\frac{1}{16} \times \frac{F_{SYS}}{12 \times (256 - TH1)}$
					Time1 ^[1] TM1 CKCON[3] = 1	$\frac{1}{16} \times \frac{F_{SYS}}{(256 - TH1)}$
					Timer 3	$\frac{1}{16} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$

Note: Timer 1 should configured as a timer in auto-reload mode (Mode 2).

Table 14.5-1 Serial Port UART0 Mode / baudrate Description

Mode	Frame Bits	SM0_1 / SM1_1 (S1CON[7:6])	SMOD_1 (T3CON[7])	Baud Rate	
0	8	00	-	FSYS divided by 12	
1	10	01	0	Timer 3	$\frac{1}{32} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
			1	Timer 3	$\frac{1}{16} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
2	11	10	0	FSYS divided by 64	
			1	FSYS divided by 32	
3	11	11	0	Timer 3	$\frac{1}{32} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$
			1	Timer 3	$\frac{1}{16} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$

Table 14.5-2 Serial Port UART1 Mode / baudrate Description

Sample code: we list the most popular UART setting Mode 1 initial step as following:

Serial port 0 (**UART0**) use **timer 1** as baudrate generator: Formula is $\frac{1}{16} \times \frac{F_{SYS}}{(256 - TH1)}$

```

SCON = 0x50;      //UART0 Mode1,REN=1,TI=1
TMOD |= 0x20;     //Timer1 set to Mode2 auto reload mode (must)
PCON |= 0x80;     //UART0 Double Rate Enable
CKCON |= 0x10;    //Timer 1 as clock source
T3CON &= 0xDF;    //Timer1 as UART0 clock source
TH1 = value;
TR1=1;

```

Serial port 0 (**UART0**) use **Timer 3** as baudrate generator: Formula is

$$\frac{1}{16} \times \frac{F_{SYS}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$$

```

SCON = 0x50;      //UART0 Mode1,REN=1,TI=1
PCON |= 0x80;     //UART0 Double Rate Enable
T3CON &= 0xF8;    //(Prescale=1)
T3CON |= 0x20;    //UART0 baud rate clock source = Timer3
RH3 = value high byte
RL3 = value low byte
T3CON|= 0x08;     //Trigger Timer3

```

Serial port 1 (UART1) use Timer 3 as baudrate generator: Formula is

$$\frac{1}{16} \times \frac{F_{sys}}{\text{Pre-scale} \times (65536 - (256 \times RH3 + RL3))}$$

```
SCON_1 = 0x52;    //UART1 Mode1,REN_1=1,TI_1=1
T3CON = 0xF8;     //T3PS2=0,T3PS1=0,T3PS0=0 (Prescale=1),
RH3 = value high byte
RL3 = value low byte
T3CON|= 0x08;
```

Following list some popular baudrate value base on different Fsys and the deviation value:

Fsys Value	Baud Rate	TH1 Value (Hex)	RH3,RL3 Value (Hex)	Baudrate Deviation
24MHz	4800	64 (SMOD=0)	FEC8	0.160256%
	9600	64	FF64	0.160256%
	19200	B2	FFB2	0.160256%
	38400	D9	FFD9	0.160256%
	57600	E6	FFE6	0.160256%
	115200	F3	FFF3	0.160256%
	150000	F6	FFF6	0.000000%
	166666	F7	FFF7	0.000400%
	187500	F8	FFF8	0.000000%
	214285	F9	FFF9	0.000333%
	250000	FA	FFFA	0.000000%
	300000	FB	FFFB	0.000000%
	375000	FC	FFFC	0.000000%
	500000	FD	FFFD	0.000000%
	750000	FE	FFFE	0.000000%
	1500000	FF	FFFF	0.000000%
16MHz	4800	30	FF30	0.160256%
	9600	98	FF98	0.160256%
	19200	CC	FFCC	0.160256%
	38400	E6	FFE6	0.160256%
	57600	EF	FFE6	2.124183%
	115200	F7	FFF7	-3.549383%
	200000	FB	FFFB	0.000000%
	250000	FC	FFFC	0.000000%

Fsys Value	Baud Rate	TH1 Value (Hex)	RH3,RL3 Value (Hex)	Baudrate Deviation
	333333	FD	FFFD	0.000100%
	500000	FE	FFFE	0.000000%
	1000000	FF	FFFF	0.000000%

14.6 Framing Error Detection

Framing error detection is provided for asynchronous modes. (Mode 1, 2, or 3.) The framing error occurs when a valid stop bit is not detected due to the bus noise or contention. The UART can detect a framing error and notify the software.

The framing error bit, FE, is located in SCON.7. This bit normally serves as SM0. While the framing error accessing enable bit SMOD0 (PCON.6) is set 1, it serves as FE flag. Actually, SM0 and FE locate in different registers.

The FE bit will be set 1 via hardware while a framing error occurs. FE can be checked in UART interrupt service routine if necessary. Note that SMOD0 should be 1 while reading or writing to FE. If FE is set, any following frames received without frame error will not clear the FE flag. The clearing has to be done via software.

14.7 Multiprocessor Communication

The MS51 multiprocessor communication feature lets a master device send a multiple frame serial message to a slave device in a multi-slave configuration. It does this without interrupting other slave devices that may be on the same serial line. This feature can be used only in UART Mode 2 or 3. User can enable this function by setting SM2 (SCON.5) as logic 1 so that when a byte of frame is received, the serial interrupt will be generated only if the 9th bit is 1. (For Mode 2, the 9th bit is the stop bit.) When the SM2 bit is 1, serial data frames that are received with the 9th bit as 0 do not generate an interrupt. In this case, the 9th bit simply separates the slave address from the serial data.

When the master device wants to transmit a block of data to one of several slaves on a serial line, it first sends out an address byte to identify the target slave. Note that in this case, an address byte differs from a data byte. In an address byte, the 9th bit is 1 and in a data byte, it is 0. The address byte interrupts all slaves so that each slave can examine the received byte and see if it is addressed by its own slave address. The addressed slave then clears its SM2 bit and prepares to receive incoming data bytes. The SM2 bits of slaves that were not addressed remain set, and they continue operating normally while ignoring the incoming data bytes.

Follow the steps below to configure multiprocessor communications:

1. Set all devices (masters and slaves) to UART Mode 2 or 3.

2. Write the SM2 bit of all the slave devices to 1.
3. The master device's transmission protocol is:
 - First byte: the address, identifying the target slave device, (9th bit = 1).
 - Next bytes: data, (9th bit = 0).
4. When the target slave receives the first byte, all of the slaves are interrupted because the 9th data bit is 1. The targeted slave compares the address byte to its own address and then clears its SM2 bit to receiving incoming data. The other slaves continue operating normally.
5. After all data bytes have been received, set SM2 back to 1 to wait for next address.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. For Mode 1 reception, if SM2 is 1, the receiving interrupt will not be issue unless a valid stop bit is received.

14.8 Automatic Address Recognition

The automatic address recognition is a feature, which enhances the multiprocessor communication feature by allowing the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address, which passes by the serial port. Only when the serial port recognizes its own address, the receiver sets RI bit to request an interrupt. The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled, SM2 is set.

If desired, user may enable the automatic address recognition feature in Mode 1. In this configuration, the stop bit takes the place of the ninth data bit. RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

Using the automatic address recognition feature allows a master to selectively communicate with one or more slaves by invoking the "Given" slave address or addresses. All of the slaves may be contacted by using the "Broadcast" address. Two SFR are used to define the slave address, SADDR, and the slave address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the SADDR to create the "Given" address, which the master will use for addressing each of the slaves. Use of the "Given" address allows multiple slaves to be recognized while excluding others.

The following examples will help to show the versatility of this scheme.

Example 1, slave 0:

```
SADDR = 11000000b
SADEN = 11111101b
Given = 110000X0b
```

Example 2, slave 1:

```
SADDR = 11000000b
SADEN = 11111110b
Given = 110000XB
```

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires 0 in bit 0 and it ignores bit 1. Slave 1 requires 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires 0 in bit 1. A unique address for slave 1 would be 11000001b since 1 in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address, which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 11000000b as their "Broadcast" address.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

Example 1, slave 0:

```
SADDR = 11000000b
SADEN = 11111001b
Given = 11000XX0b
```

Example 2, slave 1:

```
SADDR = 11100000b
SADEN = 11111010b
Given = 11100X0Xb
```

Example 3, slave 2:

```
SADDR = 11000000b
SADEN = 11111100b
Given = 110000XXb
```

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 11100110b. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 11100101b. Slave 2 requires that bit 2 = 0 and its unique address

is 11100011b. To select Slaves 0 and 1 and exclude Slave 2 use address 11100100b, since it is necessary to make bit 2 = 1 to exclude slave 2.

The “Broadcast” address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated as “don’t-cares”, e.g.:

SADDR = 01010110b

SADEN = 11111100b

Broadcast = 1111111Xb

The use of don’t-care bits provides flexibility in defining the Broadcast address, however in most applications, interpreting the “don’t-cares” as all ones, the broadcast address will be FFH.

On reset, SADDR and SADEN are initialized to 00H. This produces a “Given” address of all “don’t cares” as well as a “Broadcast” address of all XXXXXXXXb (all “don’t care” bits). This ensures that the serial port will reply to any address, and so that it is backwards compatible with the standard 80C51 microcontrollers that do not support automatic address recognition.

14.9 Serial Port Register Description

SCON – Serial Port Control (Bit-addressable)

7	6	5	4	3	2	1	0
SM0/FE	SM1	SM2	REN	TB8	RB8	TI	RI
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 98H, All pages Reset value: 0000 0000b

Bit	Name	Description
7	SM0/FE	Serial port mode select SMOD0 (PCON.6) = 0:
6	SM1	See Table 14.5-1 Serial Port UART0 Mode / baudrate Description for details. SMOD0 (PCON.6) = 1: SM0/FE bit is used as frame error (FE) status flag. It is cleared by software. 0 = Frame error (FE) did not occur. 1 = Frame error (FE) occurred and detected.
5	SM2	Multiprocessor communication mode enable The function of this bit is dependent on the serial port 0 mode. Mode 0: This bit select the baud rate between FSYS/12 and FSYS/2. 0 = The clock runs at FSYS/12 baud rate. It maintains standard 8051 compatibility. 1 = The clock runs at FSYS/2 baud rate for faster serial communication. Mode 1: This bit checks valid stop bit. 0 = Reception is always valid no matter the logic level of stop bit. 1 = Reception is valid only when the received stop bit is logic 1 and the received data matches "Given" or "Broadcast" address. Mode 2 or 3: For multiprocessor communication. 0 = Reception is always valid no matter the logic level of the 9th bit. 1 = Reception is valid only when the received 9th bit is logic 1 and the received data matches "Given" or "Broadcast" address.
4	REN	Receiving enable 0 = Serial port 0 reception Disabled. 1 = Serial port 0 reception Enabled in Mode 1,2, or 3. In Mode 0, reception is initiated by the condition REN = 1 and RI = 0.
3	TB8	9th transmitted bit This bit defines the state of the 9th transmission bit in serial port 0 Mode 2 or 3. It is not used in Mode 0 or 1.
2	RB8	9th received bit The bit identifies the logic level of the 9th received bit in serial port 0 Mode 2 or 3. In Mode 1, RB8 is the logic level of the received stop bit. SM2 bit as logic 1 has restriction for exception. RB8 is not used in Mode 0.

Bit	Name	Description
1	TI	Transmission interrupt flag This flag is set by hardware when a data frame has been transmitted by the serial port 0 after the 8th bit in Mode 0 or the last data bit in other modes. When the serial port 0 interrupt is enabled, setting this bit causes the CPU to execute the serial port 0 interrupt service routine. This bit should be cleared manually via software.
0	RI	Receiving interrupt flag This flag is set via hardware when a data frame has been received by the serial port 0 after the 8th bit in Mode 0 or after sampling the stop bit in Mode 1, 2, or 3. SM2 bit as logic 1 has restriction for exception. When the serial port 0 interrupt is enabled, setting this bit causes the CPU to execute to the serial port 0 interrupt service routine. This bit should be cleared manually via software.

Note that TXD and RXD will exchange immediately once setting or clearing this bit. User should take care of not exchanging pins during transmission or receiving. Or it may cause unpredictable situation and no warning alarms.

15 SERIAL PERIPHERAL INTERFACE (SPI)

The MS51 provides two Serial Peripheral Interface (SPI) block to support high-speed serial communication. SPI is a full-duplex, high-speed, synchronous communication bus between microcontrollers or other peripheral devices such as serial EEPROM, LCD driver, or D/A converter. It provides either Master or Slave mode, high-speed rate up to $F_{SYS}/4$, transfer complete and write collision flag. For a multi-master system, SPI supports Master Mode Fault to protect a multi-master conflict.

15.1 Functional Description

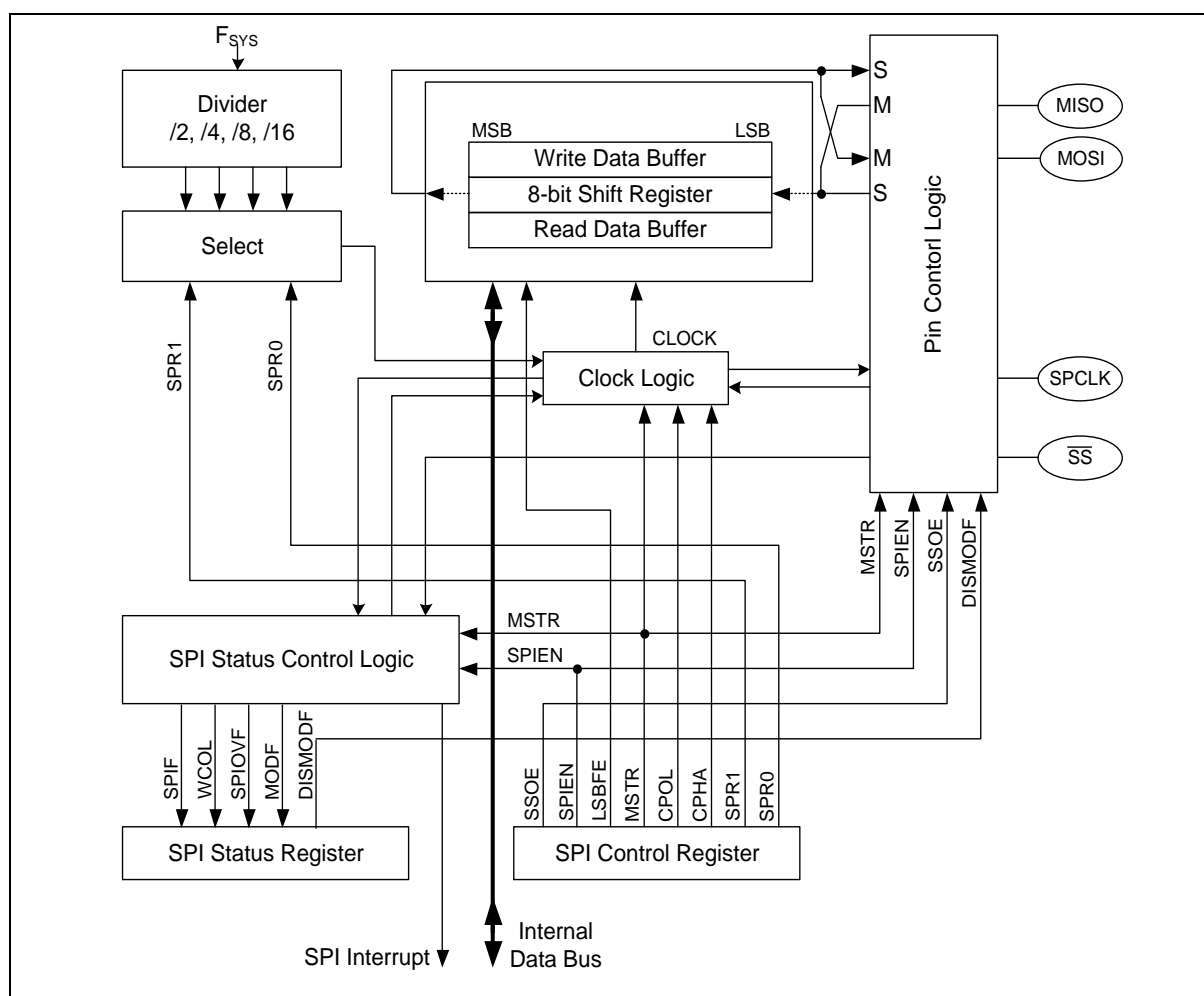

Figure 15.1-1 SPI Block Diagram

Figure 15.1 SPI Block Diagram shows SPI block diagram. It provides an overview of SPI architecture in this device. The main blocks of SPI are the SPI control register logic, SPI status logic, clock rate control logic, and pin control logic. For a serial data transfer or receiving, The SPI block exists a write data buffer, a shift out register and a read data buffer. It is double buffered in the receiving and transmit directions. Transmit data can be written to the shifter until when the previous transfer is not

complete. Receiving logic consists of parallel read data buffer so the shift register is free to accept a second data, as the first received data will be transferred to the read data buffer.

The four pins of SPI interface are Master-In/Slave-Out (MISO), Master-Out/Slave-In (MOSI), Shift Clock (SPCLK), and Slave Select (\overline{SS}). The MOSI pin is used to transfer a 8-bit data in series from the Master to the Slave. Therefore, MOSI is an output pin for Master device and an input for Slave. Respectively, the MISO is used to receive a serial data from the Slave to the Master.

The SPCLK pin is the clock output in Master mode, but is the clock input in Slave mode. The shift clock is used to synchronize the data movement both in and out of the devices through their MOSI and MISO pins. The shift clock is driven by the Master mode device for eight clock cycles. Eight clocks exchange one byte data on the serial lines. For the shift clock is always produced out of the Master device, the system should never exist more than one device in Master mode for avoiding device conflict.

Each Slave peripheral is selected by one Slave Select pin (\overline{SS}). The signal should stay low for any Slave access. When \overline{SS} is driven high, the Slave device will be inactivated. If the system is multi-slave, there should be only one Slave device selected at the same time. In the Master mode MCU, the \overline{SS} pin does not function and it can be configured as a general purpose I/O. However, \overline{SS} can be used as Master Mode Fault detection (see chapter 15.5 Mode Fault Detection) via software setting if multi-master environment exists. The MS51 also provides auto-activating function to toggle \overline{SS} between each byte-transfer.

Figure 15.1-2 SPI Multi-Master, Multi-Slave Interconnection

Figure 15.1-2 shows a typical interconnection of SPI devices. The bus generally connects devices together through three signal wires, MOSI to MOSI, MISO to MISO, and SPCLK to SPCLK. The

Master devices select the individual Slave devices by using four pins of a parallel port to control the four \overline{SS} pins. MCU1 and MCU2 play either Master or Slave mode. The \overline{SS} should be configured as Master Mode Fault detection to avoid multi-master conflict.

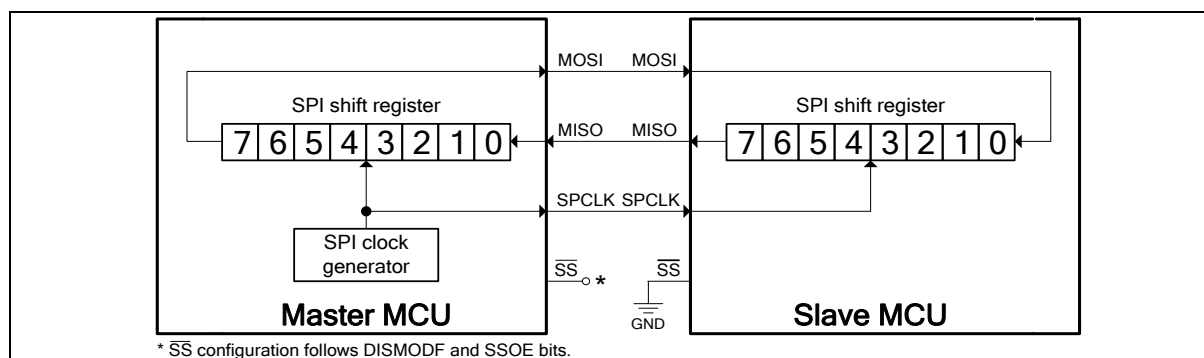

Figure 15.1-3 SPI Single-Master, Single-Slave Interconnection

Figure 15.1-3 shows the simplest SPI system interconnection, single-master and signal-slave. During a transfer, the Master shifts data out to the Slave via MOSI line. While simultaneously, the Master shifts data in from the Slave via MISO line. The two shift registers in the Master MCU and the Slave MCU can be considered as one 16-bit circular shift register. Therefore, while a transfer data pushed from Master into Slave, the data in Slave will also be pulled in Master device respectively. The transfer effectively exchanges the data, which was in the SPI shift registers of the two MCUs.

By default, SPI data is transferred MSB first. If the LSBFE (SPCR.5) is set, SPI data shifts LSB first. This bit does not affect the position of the MSB and LSB in the data register. Note that all the following description and figures are under the condition of LSBFE logic 0. MSB is transmitted and received first.

There are three SPI registers to support its operations, including SPI control register (SPCR), SPI status register (SPSR), and SPI data register (SPDR). These registers provide control, status, data storage functions, and clock rate selection. The following registers relate to SPI function.

SPSR – Serial Peripheral Status Register

7	6	5	4	3	2	1	0
SPIF	WCOL	SPIOVF	MODF	DISMODF	TXBUF	-	-
R/W	R/W	R/W	R/W	R/W	R	-	-

Address: F4H Reset value: 0000 0000b

Bit	Name	Description
7	SPIF	SPI complete flag This bit is set to logic 1 via hardware while an SPI data transfer is complete or an receiving data has been moved into the SPI read buffer. If ESPI (EIE .0) and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software. Attempting to write to SPDR is inhibited if SPIF is set.
6	WCOL	Write collision error flag This bit indicates a write collision event. Once a write collision event occurs, this bit will be set. It should be cleared via software.
5	SPIOVF	SPI overrun error flag This bit indicates an overrun event. Once an overrun event occurs, this bit will be set. If ESPI and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software.
4	MODF	Mode Fault error flag This bit indicates a Mode Fault error event. If \overline{SS} pin is configured as Mode Fault input (MSTR = 1 and DISMODF = 0) and \overline{SS} is pulled low by external devices, a Mode Fault error occurs. Instantly MODF will be set as logic 1. If ESPI and EA are enabled, an SPI interrupt will be required. This bit should be cleared via software.
3	DISMODF	Disable Mode Fault error detection This bit is used in combination with the SSOE (SPCR.7) bit to determine the feature of \overline{SS} pin as shown in Table 15.1-1 Slave Select Pin Configurations . DISMODF is valid only in Master mode (MSTR = 1). 0 = Mode Fault detection Enabled. \overline{SS} serves as input pin for Mode Fault detection disregard of SSOE. 1 = Mode Fault detection Disabled. The feature of \overline{SS} follows SSOE bit.
2	TXBUF	SPI writer data buffer status This bit indicates the SPI transmit buffer status. 0 = SPI writer data buffer is empty 1 = SPI writer data buffer is full.

SPDR – Serial Peripheral Data Register

7	6	5	4	3	2	1	0
SPDR[7:0]							
R/W							

Address: F5H Reset value: 0000 0000b

Bit	Name	Description
7:0	SPDR[7:0]	Serial peripheral data This byte is used for transmitting or receiving data on SPI bus. A write of this byte is a write to the shift register. A read of this byte is actually a read of the read data buffer. In Master mode, a write to this register initiates transmission and reception of a byte simultaneously.

15.2 Operating Modes

15.2.1 Master Mode

The SPI can operate in Master mode while MSTR (SPInCR.4) is set as 1. Only one Master SPI device can initiate transmissions. A transmission always begins by Master through writing to SPInDR. The byte written to SPInDR begins shifting out on MOSI pin under the control of SPCLK. Simultaneously, another byte shifts in from the Slave on the MISO pin. After 8-bit data transfer complete, SPIF (SPInSR.7) will automatically set via hardware to indicate one byte data transfer complete. At the same time, the data received from the Slave is also transferred in SPInDR. User can clear SPIF and read data out of SPInDR.

15.2.2 Slave Mode

When MSTR is 0, the SPI operates in Slave mode. The SPCLK pin becomes input and it will be clocked by another Master SPI device. The \overline{SS} pin also becomes input. The Master device cannot exchange data with the Slave device until the \overline{SS} pin of the Slave device is externally pulled low. Before data transmissions occurs, the \overline{SS} of the Slave device should be pulled and remain low until the transmission is complete. If \overline{SS} goes high, the SPI is forced into idle state. If the \overline{SS} is forced to high at the middle of transmission, the transmission will be aborted and the rest bits of the receiving shifter buffer will be high and goes into idle state.

In Slave mode, data flows from the Master to the Slave on MOSI pin and flows from the Slave to the Master on MISO pin. The data enters the shift register under the control of the SPCLK from the Master device. After one byte is received in the shift register, it is immediately moved into the read data buffer and the SPIF bit is set. A read of the SPInDR is actually a read of the read data buffer. To prevent an overrun and the loss of the byte that caused by the overrun, the Slave should read SPInDR out and the first SPIF should be cleared before a second transfer of data from the Master device comes in the read data buffer.

15.3 Clock Formats and Data Transfer

To accommodate a wide variety of synchronous serial peripherals, the SPI has a clock polarity bit CPOL (SPInCR.3) and a clock phase bit CPHA (SPInCR.2). Figure 15.3-1 SPI Clock Formats shows that CPOL and CPHA compose four different clock formats. The CPOL bit denotes the SPCLK line level in its idle state. The CPHA bit defines the edge on which the MOSI and MISO lines are sampled. The CPOL and CPHA should be identical for the Master and Slave devices on the same system. To Communicate in different data formats with one another will result undetermined result.

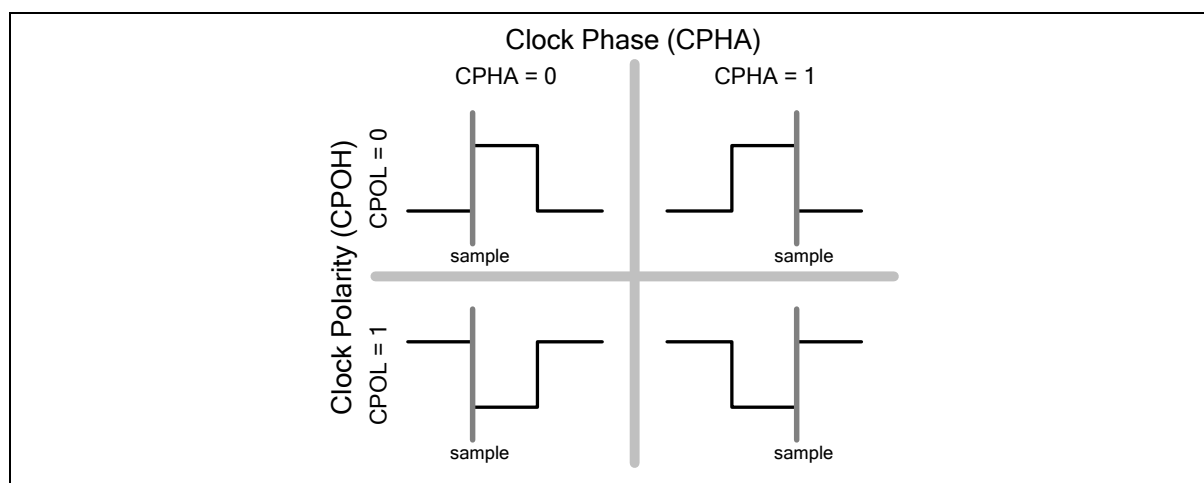

Figure 15.3-1 SPI Clock Formats

In SPI, a Master device always initiates the transfer. If SPI is selected as Master mode (MSTR = 1) and enabled (SPIEN = 1), writing to the SPI data register (SPInDR) by the Master device starts the SPI clock and data transfer. After shifting one byte out and receiving one byte in, the SPI clock stops and SPIF (SPInSR.7) is set in both Master and Slave. If SPI interrupt enable bit is set 1 and global interrupt is enabled (EA = 1), the interrupt service routine (ISR) of SPI will be executed.

Concerning the Slave mode, the \overline{SS} signal needs to be taken care. As shown in Figure 15.3-1 SPI Clock Formats, when CPHA = 0, the first SPCLK edge is the sampling strobe of MSB (for an example of LSBFE = 0, MSB first). Therefore, the Slave should shift its MSB data before the first SPCLK edge. The falling edge of \overline{SS} is used for preparing the MSB on MISO line. The \overline{SS} pin therefore should toggle high and then low between each successive serial byte. Furthermore, if the slave writes data to the SPI data register (SPInDR) while \overline{SS} is low, a write collision error occurs.

When CPHA = 1, the sampling edge thus locates on the second edge of SPCLK clock. The Slave uses the first SPCLK clock to shift MSB out rather than the \overline{SS} falling edge. Therefore, the \overline{SS} line can remain low between successive transfers. This format may be preferred in systems having single fixed Master and single fixed Slave. The \overline{SS} line of the unique Slave device can be tied to GND as long as only CPHA = 1 clock mode is used.

Note: The SPI should be configured before it is enabled (SPIEN = 1), or a change of LSBFE, MSTR, CPOL, CPHA and SPR[1:0] will abort a transmission in progress and force the SPI system into idle state. Prior to any configuration bit changed, SPIEN must be disabled first.

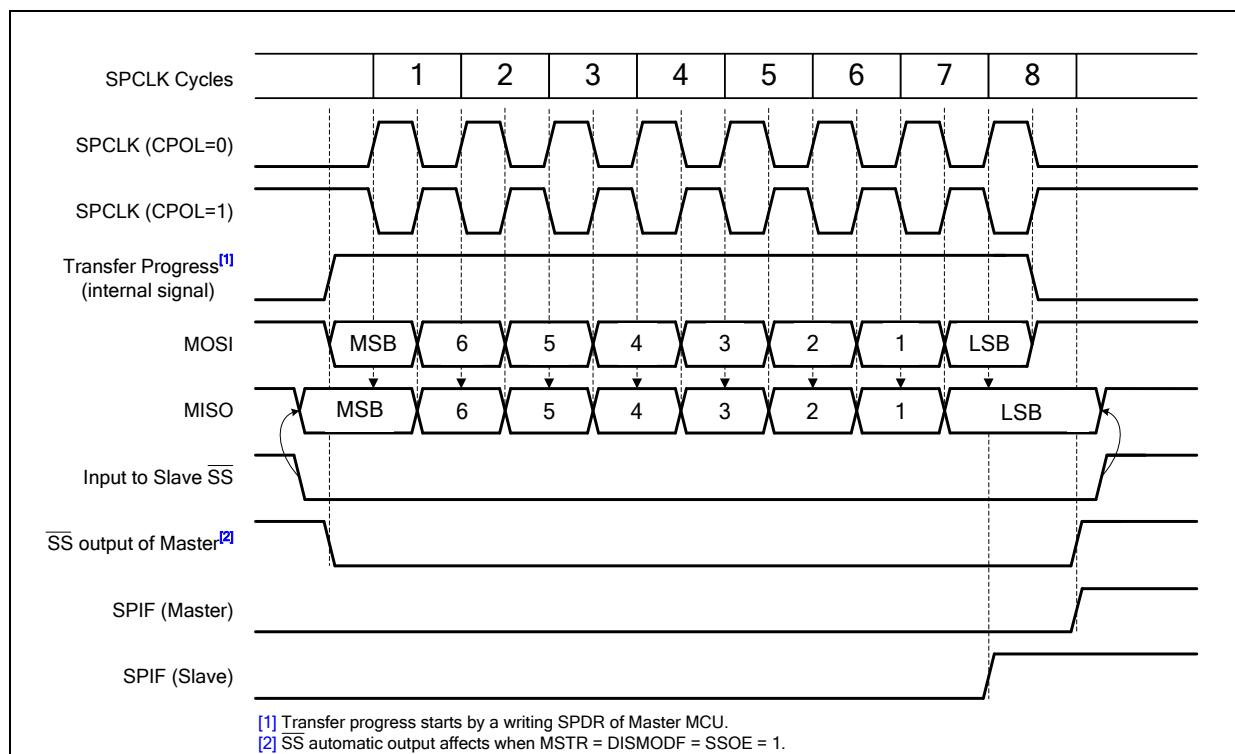

Figure 15.3-2 SPI Clock and Data Format with CPHA = 0

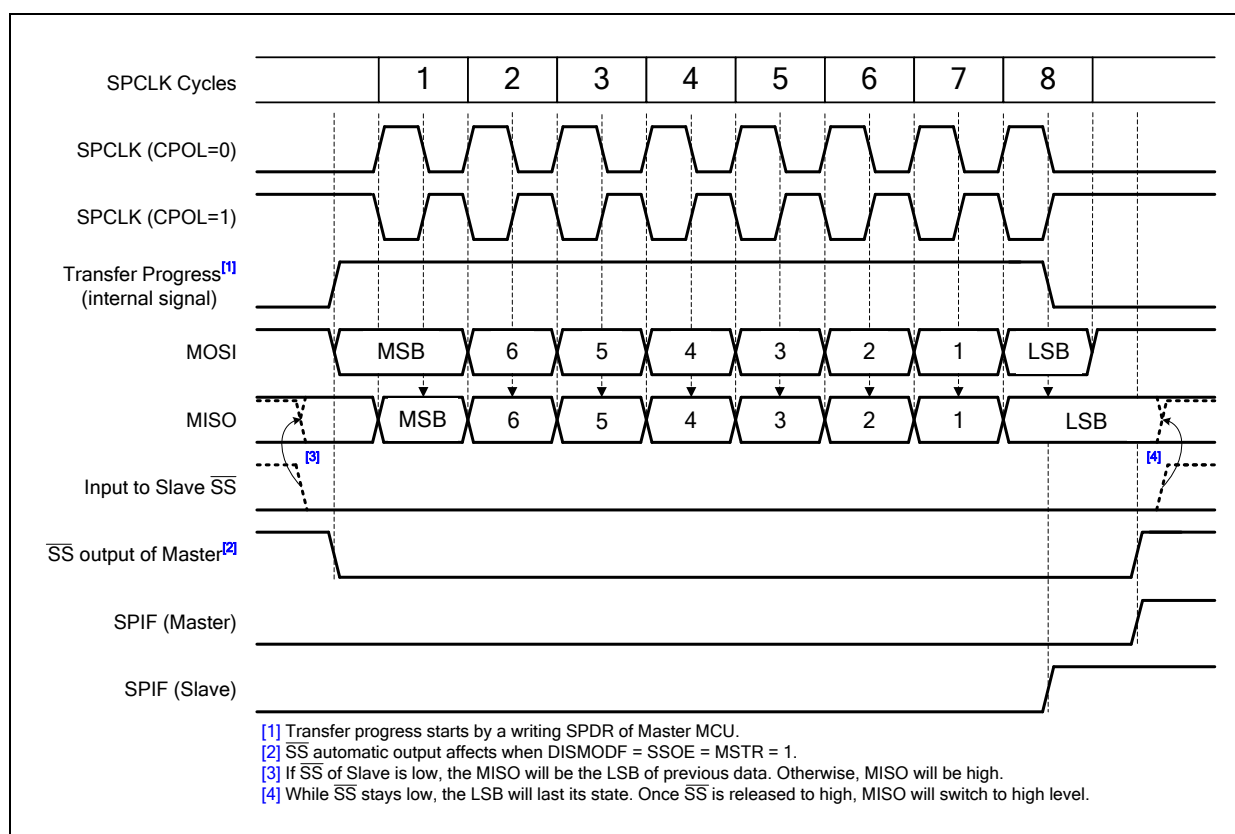

Figure 15.3-3 SPI Clock and Data Format with CPHA = 1

15.4 Slave Select Pin Configuration

The MS51 SPI gives a flexible \overline{SS} pin feature for different system requirements. When the SPI operates as a Slave, \overline{SS} pin always rules as Slave select input. When the Master mode is enabled, \overline{SS} has three different functions according to DISMODF (SPInSR.3) and SSOE (SPInCR.7). By default, DISMODF is 0. It means that the Mode Fault detection activates. \overline{SS} is configured as a input pin to check if the Mode Fault appears. On the contrary, if DISMODF is 1, Mode Fault is inactivated and the SSOE bit takes over to control the function of the \overline{SS} pin. While SSOE is 1, it means the Slave select signal will generate automatically to select a Slave device. The \overline{SS} as output pin of the Master usually connects with the \overline{SS} input pin of the Slave device. The \overline{SS} output automatically goes low for each transmission when selecting external Slave device and goes high during each idle state to de-select the Slave device. While SSOE is 0 and DISMODF is 1, \overline{SS} is no more used by the SPI and reverts to be a general purpose I/O pin.

15.5 Mode Fault Detection

The Mode Fault detection is useful in a system where more than one SPI devices might become Masters at the same time. It may induce data contention. When the SPI device is configured as a Master and the \overline{SS} input line is configured for Mode Fault input depending on Table 15.1-1 Slave

Select Pin Configurations, a Mode Fault error occurs once the \overline{SS} is pulled low by others. It indicates that some other SPI device is trying to address this Master as if it is a Slave. Instantly the MSTR and SPIEN control bits in the SPInCR are cleared via hardware to disable SPI, Mode Fault flag MODF (SPInSR.4) is set and an interrupt is generated if ESPI and EA are enabled.

15.6 Write Collision Error

The SPI is signal buffered in the transfer direction and double buffered in the receiving and transmit direction. New data for transmission cannot be written to the shift register until the previous transaction is complete. Write collision occurs while SPInDR be written more than once while a transfer was in progress. SPInDR is double buffered in the transmit direction. Any writing to SPInDR cause data to be written directly into the SPI shift register. Once a write collision error is generated, WCOL (SPInSR.6) will be set as 1 via hardware to indicate a write collision. In this case, the current transferring data continues its transmission. However the new data that caused the collision will be lost. Although the SPI logic can detect write collisions in both Master and Slave modes, a write collision is normally a Slave error because a Slave has no indicator when a Master initiates a transfer. During the receiving of Slave, a write to SPInDR causes a write collision in Slave mode. WCOL flag needs to be cleared via software.

15.7 Overrun Error

For receiving data, the SPI is double buffered in the receiving direction. The received data is transferred into a parallel read data buffer so the shifter is free to accept a second serial byte. However, the received data should be read from SPInDR before the next data has been completely shifted in. As long as the first byte is read out of the read data buffer and SPIF is cleared before the next byte is ready to be transferred, no overrun error condition occurs. Otherwise the overrun error occurs. In this condition, the second byte data will not be successfully received into the read data register and the previous data will remains. If overrun occur, SPIOVF (SPInSR.5) will be set via hardware. An SPIOVF setting will also require an interrupt if enabled. Figure 15.7-1 SPI Overrun Waveform shows the relationship between the data receiving and the overrun error.

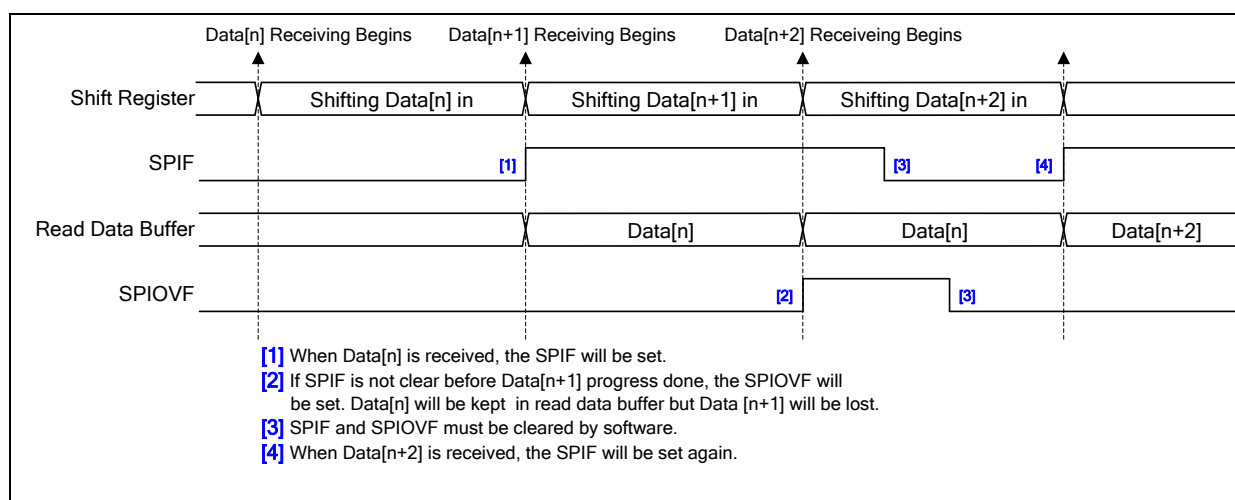

Figure 15.7-1 SPI Overrun Waveform

15.8 SPI Interrupt

Three SPI status flags, SPIF, MODF, and SPIOVF, can generate an SPI event interrupt requests. All of them locate in SPInSR. SPIF will be set after completion of data transfer with external device or a new data have been received and copied to SPInDR. MODF becomes set to indicate a low level on \overline{SS} causing the Mode Fault state. SPIOVF denotes a receiving overrun error. If SPI interrupt mask is enabled via setting ESPI and EA is 1, CPU will executes the SPI interrupt service routine once any of these three flags is set. User needs to check flags to determine what event caused the interrupt. These three flags are software cleared.

Figure 15.8-1 SPI Interrupt Request

16 INTER-INTEGRATED CIRCUIT (I²C)

The MS51 provides two Inter-Integrated Circuit (I²C) bus to serves as an serial interface between the microcontrollers and the I²C devices such as EEPROM, LCD module, temperature sensor, and so on. The I²C bus used two wires design (a serial data line I2C0_SDA and a serial clock line I2C0_SCL) to transfer information between devices.

The I²C bus uses bi-directional data transfer between masters and slaves. There is no central master and the multi-master system is allowed by arbitration between simultaneously transmitting masters. The serial clock synchronization allows devices with different bit rates to communicate via one serial bus. The I²C bus supports four transfer modes including master transmitter, master receiver, slave receiver, and slave transmitter. The I²C interface only supports 7-bit addressing mode. A special mode General Call is also available. The I²C can meet both standard (up to 100kbps) and fast (up to 400k bps) speeds.

16.1 Functional Description

For a bi-directional transfer operation, the I2C0_SDA and I2C0_SCL pins should be open-drain pads. This implements a wired-AND function, which is essential to the operation of the interface. A low level on a I²C bus line is generated when one or more I²C devices output a “0”. A high level is generated when all I²C devices output “1”, allowing the pull-up resistors to pull the line high. In MS51, user should set output latches of I2C0_SCL and I2C0_SDA. As logic 1 before enabling the I²C function by setting I2CEN.

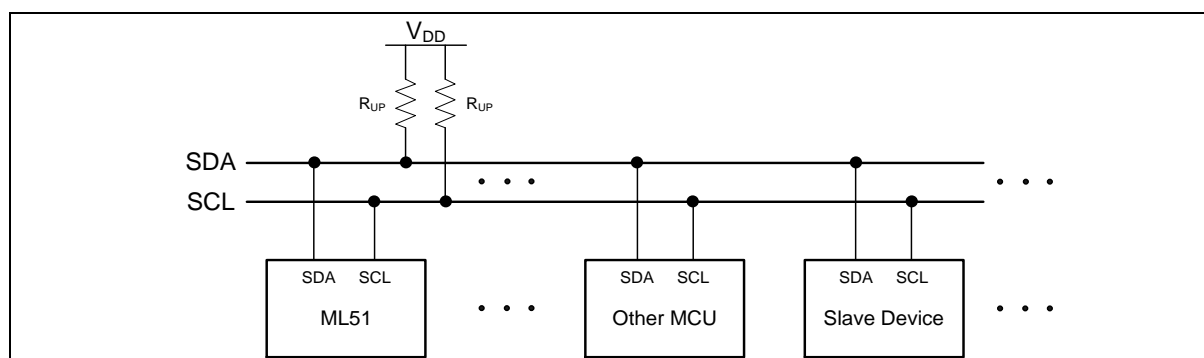

Figure 16.1-1 I²C Bus Interconnection

The I²C is considered free when both lines are high. Meanwhile, any device, which can operate as a master can occupy the bus and generate one transfer after generating a START condition. The bus now is considered busy before the transfer ends by sending a STOP condition. The master generates all of the serial clock pulses and the START and STOP condition. However if there is no START condition on the bus, all devices serve as not addressed slave. The hardware looks for its own slave

address or a General Call address. (The General Call address detection may be enabled or disabled by GC (I2CnADDRx.0).) If the matched address is received, an interrupt is requested.

Every transaction on the I²C bus is 9 bits long, consisting of 8 data bits (MSB first) and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition) is unrestricted but each byte has to be followed by an acknowledge bit. The master device generates 8 clock pulse to send the 8-bit data. After the 8th falling edge of the I2C0_SCL line, the device outputting data on the I2C0_SDA changes that pin to an input and reads in an acknowledge value on the 9th clock pulse. After 9th clock pulse, the data receiving device can hold I2C0_SCL line stretched low if next receiving is not prepared ready. It forces the next byte transaction suspended. The data transaction continues when the receiver releases the I2C0_SCL line.

Figure 16.1-2 I²C Bus Protocol

16.1.1 START and STOP Condition

The protocol of the I²C bus defines two states to begin and end a transfer, START (S) and STOP (P) conditions. A START condition is defined as a high-to-low transition on the I2C0_SDA line while I2C0_SCL line is high. The STOP condition is defined as a low-to-high transition on the I2C0_SDA line while I2C0_SCL line is high. A START or a STOP condition is always generated by the master and I²C bus is considered busy after a START condition and free after a STOP condition. After issuing the STOP condition successful, the original master device will release the control authority and turn back as a not addressed slave. Consequently, the original addressed slave will become a not addressed slave. The I²C bus is free and listens to next START condition of next transfer.

A data transfer is always terminated by a STOP condition generated by the master. However, if a master still wishes to communicate on the bus, it can generate a repeated START (Sr) condition and address the pervious or another slave without first generating a STOP condition. Various combinations of read/write formats are then possible within such a transfer.

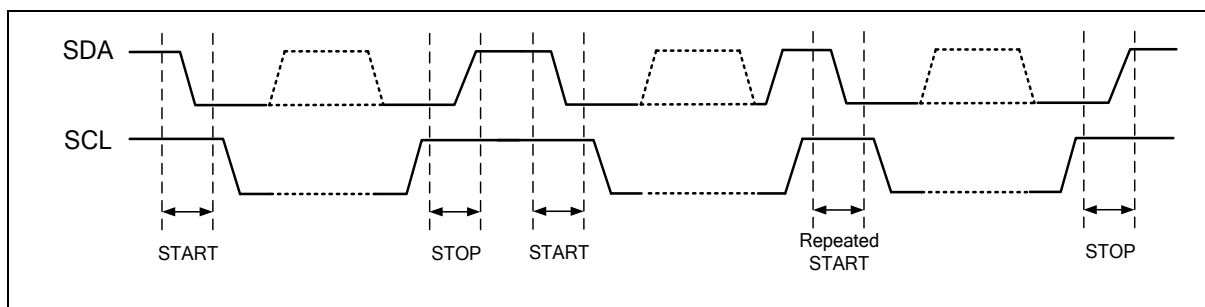

Figure 16.1-3 START, Repeated START, and STOP Conditions

16.1.2 7-Bit Address with Data Format

Following the START condition is generated, one byte of special data should be transmitted by the master. It includes a 7-bit long slave address (SLA) following by an 8th bit, which is a data direction bit (R/W), to address the target slave device and determine the direction of data flow. If R/W bit is 0, it indicates that the master will write information to a selected slave. Also, if R/W bit is 1, it indicates that the master will read information from the addressed slave. An address packet consisting of a slave address and a read I or a write (W) bit is called SLA+R or SLA+W, respectively. A transmission basically consists of a START condition, a SLA+W/R, one or more data packets and a STOP condition. After the specified slave is addressed by SLA+W/R, the second and following 8-bit data bytes issue by the master or the slave devices according to the R/W bit configuration.

Figure 16.1-4 shows a master transmits data to slave by 7-bit. A master addresses a slave with a 7-bit address and 1-bit write index to denote that the master wants to transmit data to the slave. The master keeps transmitting data after the slave returns acknowledge to the master.

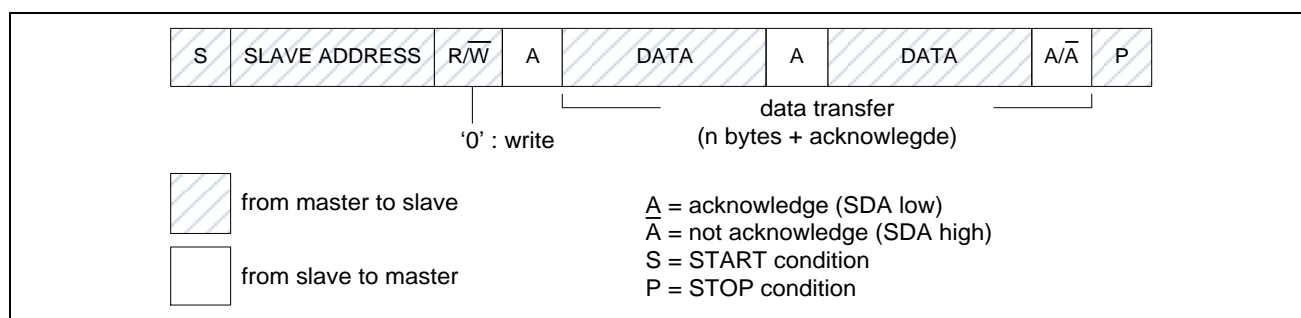

Figure 16.1-4 Master Transmits Data to Slave by 7-bit

Figure 16.1-5 shows a master read data from slave by 7-bit. A master addresses a slave with a 7-bit address and 1-bit read index to denote that the master wants to read data from the slave. The slave will start transmitting data after the slave returns acknowledge to the master.

Figure 16.1-5 Master Reads Data from Slave by 7-bit

There is an exception called “General Call” address, which can address all devices by giving the first byte of data all 0. A General Call is used when a master wishes to transmit the same message to several slaves in the system. When this address is used, other devices may respond with an acknowledge or ignore it according to individual software configuration. If a device response the General Call, it operates as like in the slave-receiver mode. Note that the address 0x00 is reserved for General Call and cannot be used as a slave address, therefore, in theory, a 7-bit addressing I^2C bus accepts 127 devices with their slave addresses 1 to 127.

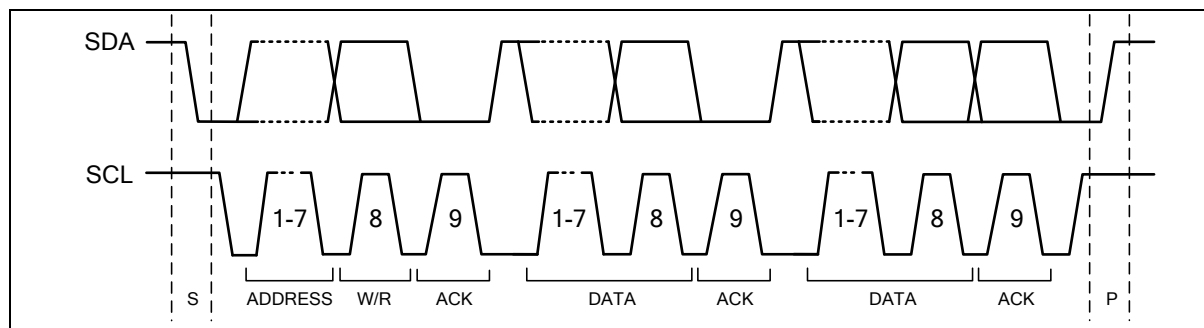

Figure 16.1-6 Data Format of One I^2C Transfer

During the data transaction period, the data on the I2C0_SDA line should be stable during the high period of the clock, and the data line can only change when I2C0_SCL is low.

16.1.3 Acknowledge

The 9th I2C0_SCL pulse for any transferred byte is dedicated as an Acknowledge (ACK). It allows receiving devices (which can be the master or slave) to respond back to the transmitter (which also can be the master or slave) by pulling the I2C0_SDA line low. The acknowledge-related clock pulse is generated by the master. The transmitter should release control of I2C0_SDA line during the acknowledge clock pulse. The ACK is an active-low signal, pulling the I2C0_SDA line low during the clock pulse high duty, indicates to the transmitter that the device has received the transmitted data. Commonly, a receiver, which has been addressed is requested to generate an ACK after each byte has been received. When a slave receiver does not acknowledge (NACK) the slave address, the I2C0_SDA line should be left high by the slave so that the master can generate a STOP or a repeated START condition.

If a slave-receiver does acknowledge the slave address, it switches itself to not addressed slave mode and cannot receive any more data bytes. This slave leaves the I2C0_SDA line high. The master should generate a STOP or a repeated START condition.

If a master-receiver is involved in a transfer, because the master controls the number of bytes in the transfer, it should signal the end of data to the slave-transmitter by not generating an acknowledge on the last byte. The slave-transmitter then switches to not addressed mode and releases the I2C0_SDA line to allow the master to generate a STOP or a repeated START condition.

Figure 16.1-7 Acknowledge Bit

16.1.4 Arbitration

A master may start a transfer only if the bus is free. It is possible for two or more masters to generate a START condition. In these situations, an arbitration scheme takes place on the I2C0_SDA line, while I2C0_SCL is high. During arbitration, the first of the competing master devices to place a '1' (high) on I2C0_SDA while another master transmits a '0' (low) switches off its data output stage because the level on the bus does not match its own level. The arbitration lost master switches to the not addressed slave immediately to detect its own slave address in the same serial transfer whether it is being addressed by the winning master. It also releases I2C0_SDA line to high level for not affecting the data transfer continued by the winning master. However, the arbitration lost master continues generating clock pulses on I2C0_SCL line until the end of the byte in which it loses the arbitration.

Arbitration is carried out by all masters continuously monitoring the I2C0_SDA line after outputting data. If the value read from the I2C0_SDA line does not match the value that the master has to output, it has lost the arbitration. Note that a master can only lose arbitration when it outputs a high I2C0_SDA value while another master outputs a low value. Arbitration will continue until only one master remains, and this may take many bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits or acknowledge bit.

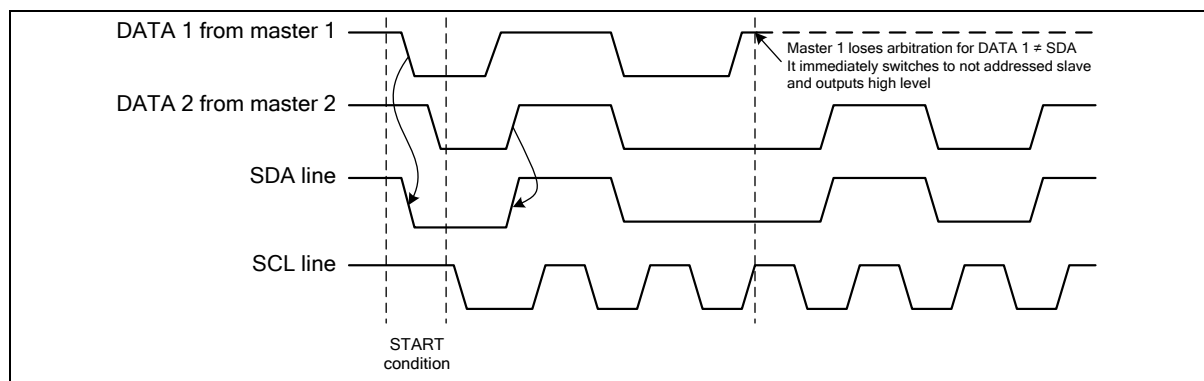

Figure 16.1-8 Arbitration Procedure of Two Masters

Since control of the I²C bus is decided solely on the address or master code and data sent by competing masters, there is no central master, nor any order of priority on the bus. Slaves are not involved in the arbitration procedure.

16.1.5 Operation Modes

The on-chip I²C ports support three operation modes, Master, Slave, and General Call Mode.

In a given application, I2C port may operate as a master or as a slave. In Slave mode, the I2C port hardware looks for its own slave address and the general call address. If one of these addresses is detected, and if the slave is willing to receive or transmit data from/to master (by setting the AA bit), acknowledge pulse will be transmitted out on the 9th clock, hence an interrupt is requested on both master and slave devices if interrupt is enabled. When the microcontroller wishes to become the bus master, hardware waits until the bus is free before entering Master mode so that a possible slave action is not be interrupted. If bus arbitration is lost in Master mode, I2C port switches to Slave mode immediately and can detect its own slave address in the same serial transfer.

To control the I2C bus transfer in each mode, user needs to set I2C_CTL0, I2C_DAT registers according to current status code of I2C_STATUS0 register. In other words, for each I2C bus action, user needs to check current status by I2C_STATUS0 register, and then set I2C_CTL0, I2C_DAT registers to take bus action. Finally, check the response status by I2C_STATUS0.

The bits, STA, STO and AA in I2C_CTL0 register are used to control the next state of the I2C hardware after SI flag of I2C_CTL0 [3] register is cleared. Upon completion of the new action, a new status code will be updated in I2C_STATUS0 register and the SI flag of I2C_CTL0 register will be set. But the SI flag will not be set when I2C STOP. If the I2C interrupt control bit INTEN (I2C_CTL0 [7]) is set, appropriate action or software branch of the new status code can be performed in the Interrupt service routine.

Figure 16.1-9 Control I²C Bus according to the Current I²C Status shows the current I2C status code is 0x08, and then set I2C_DATA=SLA+W and (STA,STO,SI,AA) = (0,0,1,x) to send the address to I2C bus. If a slave on the bus matches the address and response ACK, the I2C_STATUS0 will be updated by status code 0x18.

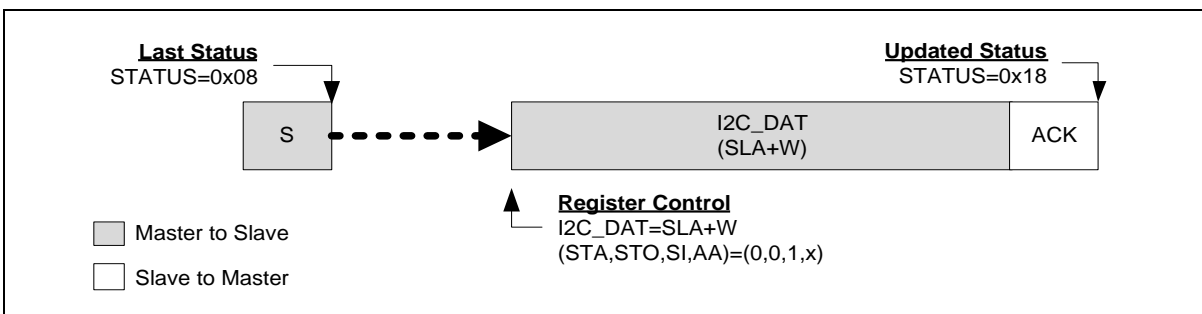

Figure 16.1-9 Control I²C Bus according to the Current I²C Status

Master Transmitter Mode

In the master transmitter mode, several bytes of data are transmitted to a slave receiver. The master should prepare by setting desired clock rate in I2CnCLK. The master transmitter mode may now be entered by setting STA (I2CnCON.5) bit as 1. The hardware will test the bus and generate a START condition as soon as the bus becomes free. After a START condition is successfully produced, the SI flag (I2CnCON.3) will be set and the status code in I2CnSTAT show 08H. The progress is continued by loading I2CnDAT with the target slave address and the data direction bit “write” (SLA+W). The SI bit should then be cleared to commence SLA+W transaction.

After the SLA+W byte has been transmitted and an acknowledge (ACK) has been returned by the addressed slave device, the SI flag is set again and I2CnSTAT is read as 18H. The appropriate action to be taken follows user defined communication protocol by sending data continuously. After all data is transmitted, the master can send a STOP condition by setting STO (I2CnCON.4) and then clearing SI to terminate the transmission. A repeated START condition can also be generated without sending STOP condition to immediately initial another transmission.

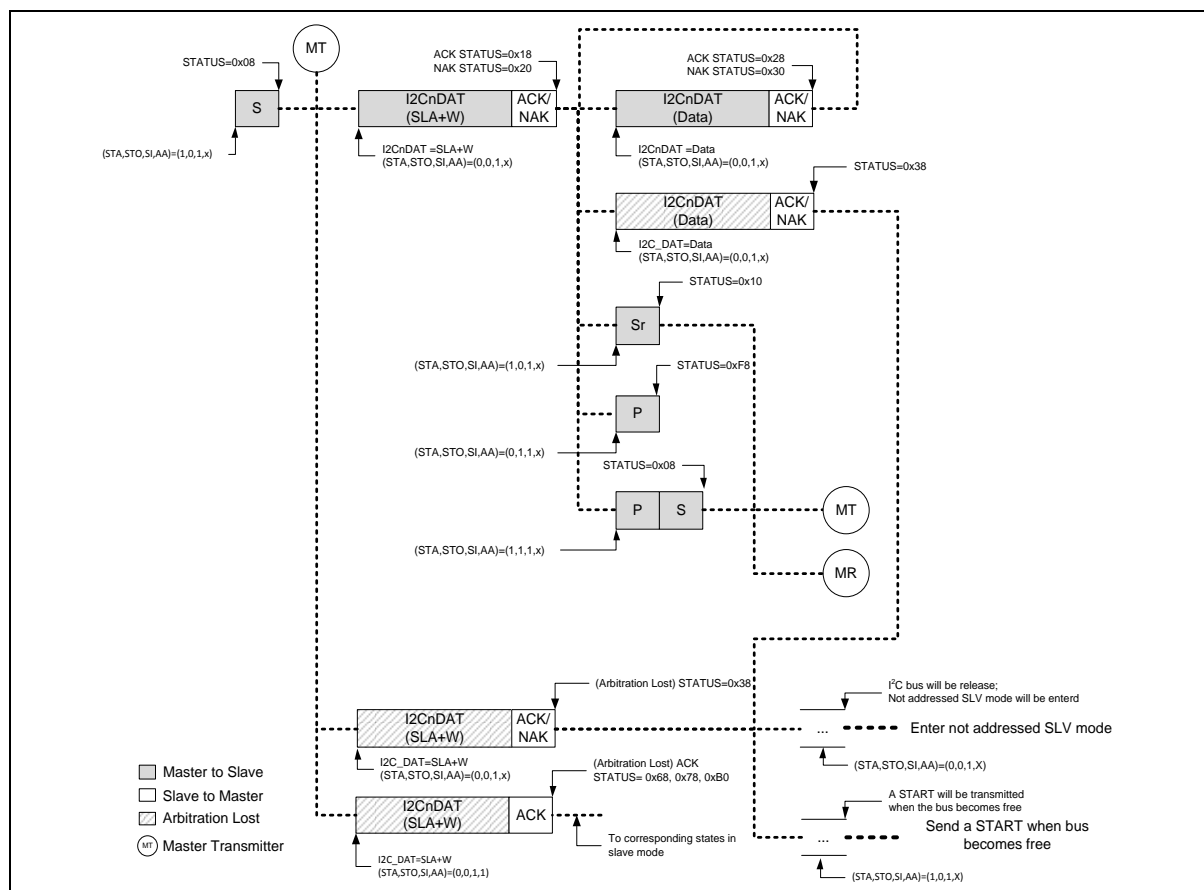

Figure 16.1-10 Flow and Status of Master Transmitter Mode

Master Receiver Mode

In the master receiver mode, several bytes of data are received from a slave transmitter. The transaction is initialized just as the master transmitter mode. Following the START condition, I2CnDAT should be loaded with the target slave address and the data direction bit “read” (SLA+R). After the SLA+R byte is transmitted and an acknowledge bit has been returned, the SI flag is set again and I2CnSTAT is read as 40H. SI flag then should be cleared to receive data from the slave transmitter. If AA flag (I2CnCON.2) is set, the master receiver will acknowledge the slave transmitter. If AA is cleared, the master receiver will not acknowledge the slave and release the slave transmitter as a not addressed slave. After that, the master can generate a STOP condition or a repeated START condition to terminate the transmission or initial another one.

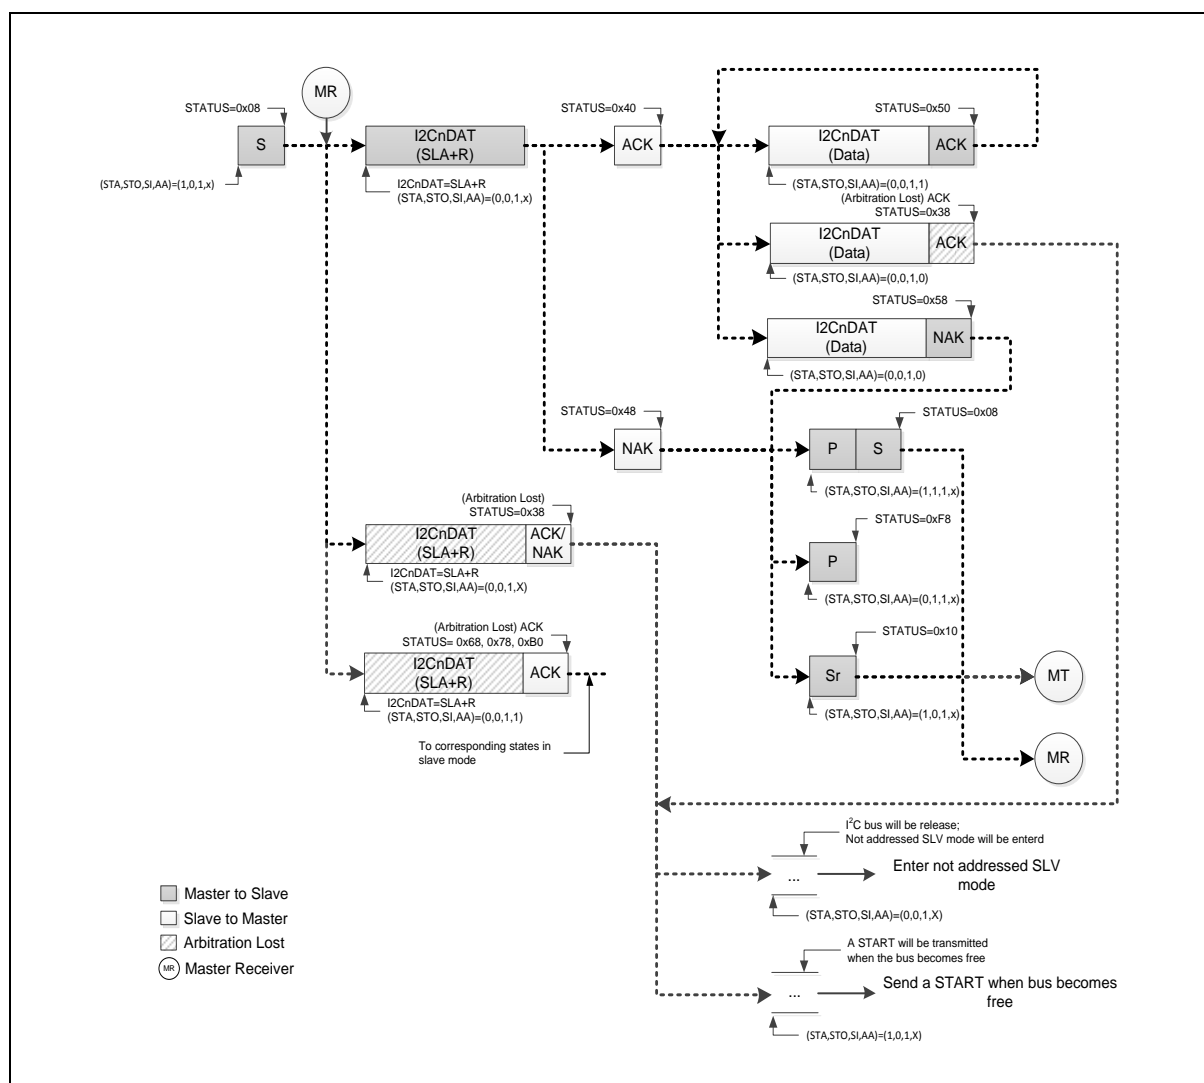

Figure 16.1-11 Flow and Status of Master Receiver Mode

Slave Receiver

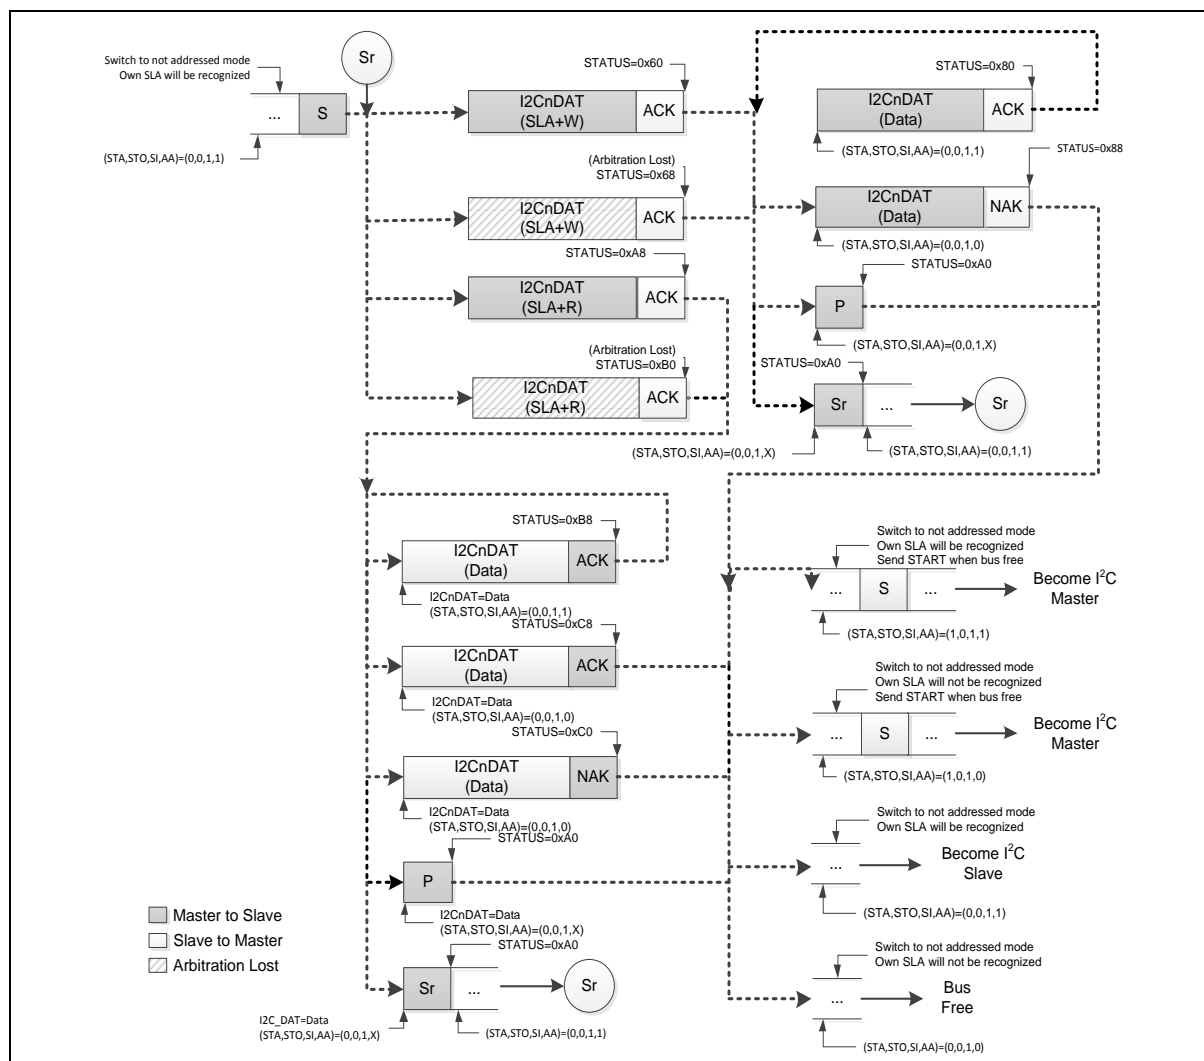

In the slave receiver mode, several bytes of data are received from a master transmitter. Before a transmission is commenced, I2CnADDRx should be loaded with the address to which the device will respond when addressed by a master. I2CnCLK does not affect in slave mode. The AA bit should be set to enable acknowledging its own slave address. After the initialization above, the I²C idles until it is addressed by its own address with the data direction bit “write” (SLA+W). The slave receiver mode may also be entered if arbitration is lost.

After the slave is addressed by SLA+W, it should clear its SI flag to receive the data from the master transmitter. If the AA bit is 0 during a transaction, the slave will return a non-acknowledge after the next received data byte. The slave will also become not addressed and isolate with the master. It cannot receive any byte of data with I2CnDAT remaining the previous byte of data, which is just received.

Slave Transmitter

The I²C port is equipped with four slave address registers, I2CnADDRx (x=0~3). The contents of the register are irrelevant when I²C is in Master mode. In the slave transmitter mode, several bytes of data are transmitted to a master receiver. After I2CnADDRx and I2CnCON values are given, the I²C wait until it is addressed by its own address with the data direction bit “read” (SLA+R). The slave transmitter mode may also be entered if arbitration is lost.

After the slave is addressed by SLA+R, it should clear its SI flag to transmit the data to the master receiver. Normally the master receiver will return an acknowledge after every bytes of data is transmitted by the slave. If the acknowledge is not received, it will transmit all “1” data if it continues the transaction. It becomes a not addressed slave. If the AA flag is cleared during a transaction, the slave transmits the last byte of data. The next transmitting data will be all “1” and the slave becomes not addressed.

General Call

The General Call is a special condition of slave receiver mode by been addressed with all “0” data in slave address with data direction bit. Both GC (I2CnADDRx.0) bit and AA bit should be set as 1 to enable acknowledging General Calls. The slave addressed by a General Call has different status code in I2CnSTAT with normal slave receiver mode. The General Call may also be produced if arbitration is lost.

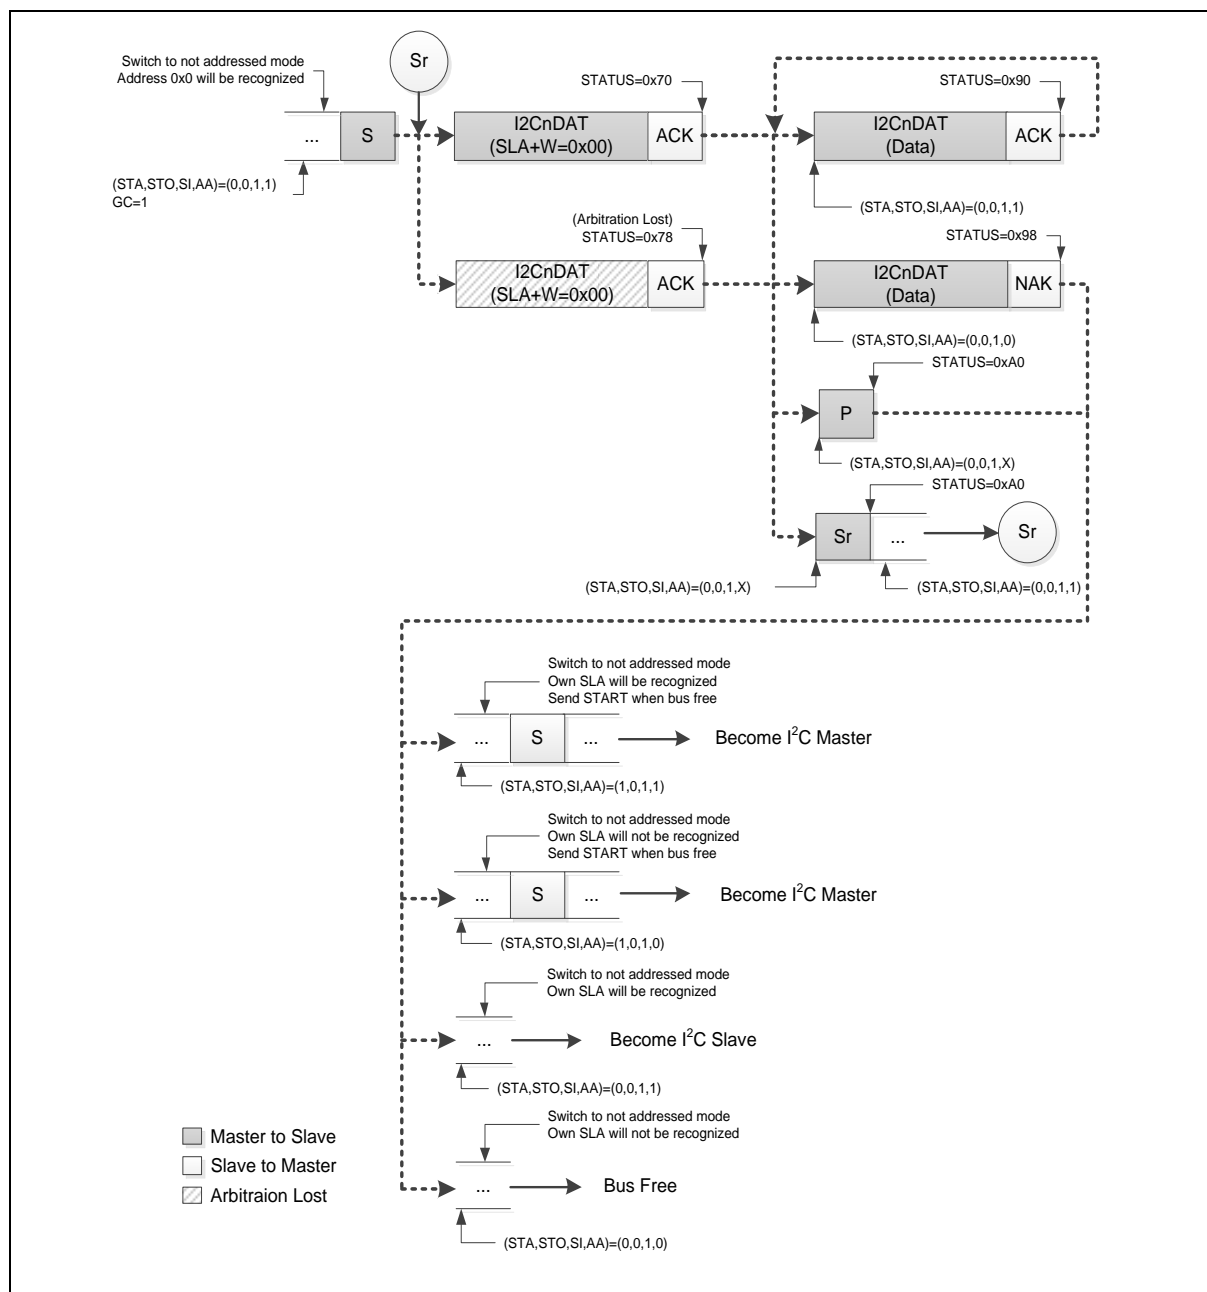

Figure 16.1-13 Flow and Status of General Call Mode

16.1.6 Miscellaneous States

There are two I2CnSTAT status codes that do not correspond to the 25 defined states, The first status code F8H indicates that no relevant information is available during each transaction. Meanwhile, the SI flag is 0 and no I²C interrupt is required. The other status code 00H means a bus error has occurred during a transaction. A bus error is caused by a START or STOP condition appearing temporally at an illegal position such as the second through eighth bits of an address or a data byte, and the acknowledge bit. When a bus error occurs, the SI flag is set immediately. When a bus error is detected on the I²C bus, the operating device immediately switches to the not addressed slave mode, releases I2C0_SDA and I2C0_SCL lines, sets the SI flag, and loads I2CnSTAT as 00H. To recover from a bus error, the STO bit should be set and then SI should be cleared. After that, STO is cleared by hardware and release the I²C bus without issuing a real STOP condition waveform on I²C bus.

There is a special case if a START or a repeated START condition is not successfully generated for I²C bus is obstructed by a low level on I2C0_SDA line e.g. a slave device out of bit synchronization, the problem can be solved by transmitting additional clock pulses on the I2C0_SCL line. The I²C hardware transmits additional clock pulses when the STA bit is set, but no START condition can be generated because the I2C0_SDA line is pulled low. When the I2C0_SDA line is eventually released, a normal START condition is transmitted, state 08H is entered, and the serial transaction continues. If a repeated START condition is transmitted while I2C0_SDA is obstructed low, the I²C hardware also performs the same action as above. In this case, state 08H is entered instead of 10H after a successful START condition is transmitted. Note that the software is not involved in solving these bus problems.

The following table is show the status display in I2STAT register of I²C number and description:

Master Mode		Slave Mode	
STATUS	Description	STATUS	Description
0x08	Start	0xA0	Slave Transmit Repeat Start or Stop
0x10	Master Repeat Start	0xA8	Slave Transmit Address ACK
0x18	Master Transmit Address ACK	0xB0	Slave Transmit Arbitration Lost
0x20	Master Transmit Address NACK	0xB8	Slave Transmit Data ACK
0x28	Master Transmit Data ACK	0xC0	Slave Transmit Data NACK
0x30	Master Transmit Data NACK	0xC8	Slave Transmit Last Data ACK
0x38	Master Arbitration Lost	0x60	Slave Receive Address ACK
0x40	Master Receive Address ACK	0x68	Slave Receive Arbitration Lost
0x48	Master Receive Address NACK	0x80	Slave Receive Data ACK
0x50	Master Receive Data ACK	0x88	Slave Receive Data NACK
0x58	Master Receive Data NACK	0x70	GC mode Address ACK
0x00	Bus error	0x78	GC mode Arbitration Lost

		0x90	GC mode Data ACK
		0x98	GC mode Data NACK
0xF8	Bus Released Note: Status "0xF8" exists in both master/slave modes, and it won't raise interrupt.		

16.2 Control Registers of I²C

There are five control registers to interface the I²C bus including I2CON, I2STAT, I2DAT, I2ADDR, and I2CLK. These registers provide protocol control, status, data transmitting and receiving functions, and clock rate configuration. For application flexibility, I2C0_SDA and I2C0_SCL pins can be exchanged by I2CPX (I2CON.0). The following registers relate to I²C function.

I2CON – I²C Control (Bit-addressable)

7	6	5	4	3	2	1	0
I	I2CEN	STA	STO	SI	AA	-	I2CPX
R/W	R/W	R/W	R/W	R/W	R/W	-	R/W

Address: C0H Reset value: 0000 0000b

Bit	Name	Description
7	I	I2C0 hold time extend enable 0 = I ² C DATA to I2C0_SCL hold time extend disabled 1 = I ² C DATA to I2C0_SCL hold time extend enabled, extend 8 system clock
6	I2CEN	I2C bus enable 0 = I ² C bus Disabled. 1 = I ² C bus Enabled. Before enabling the I2C, I2C0_SCL and I2C0_SDA port latches should be set to logic 1.
5	STA	START flag When STA is set, the I2C generates a START condition if the bus is free. If the bus is busy, the I2C waits for a STOP condition and generates a START condition following. If STA is set while the I2C is already in the master mode and one or more bytes have been transmitted or received, the I2C generates a repeated START condition. Note that STA can be set anytime even in a slave mode, but STA is not hardware automatically cleared after START or repeated START condition has been detected. User should take care of it by clearing STA manually.
4	STO	STOP flag When STO is set if the I ² C is in the master mode, a STOP condition is transmitted to the bus. STO is automatically cleared by hardware once the STOP condition has been detected on the bus. The STO flag setting is also used to recover the I ² C device from the bus error state (I2STAT as 00H). In this case, no STOP condition is transmitted to the I ² C bus. If the STA and STO bits are both set and the device is original in the master mode, the I ² C bus will generate a STOP condition and immediately follow a START condition. If the device is in slave mode, STA and STO simultaneous setting should be avoided from issuing illegal I ² C frames.

Bit	Name	Description
3	SI	<p>I²C interrupt flag</p> <p>SI flag is set by hardware when one of 26 possible I²C status (besides F8H status) is entered. After SI is set, the software should read I2STAT register to determine which step has been passed and take actions for next step.</p> <p>SI is cleared by software. Before the SI is cleared, the low period of I2C0_SCL line is stretched. The transaction is suspended. It is useful for the slave device to deal with previous data bytes until ready for receiving the next byte.</p> <p>The serial transaction is suspended until SI is cleared by software. After SI is cleared, I²C bus will continue to generate START or repeated START condition, STOP condition, 8-bit data, or so on depending on the software configuration of controlling byte or bits. Therefore, user should take care of it by preparing suitable setting of registers before SI is software cleared.</p>
2	AA	<p>Acknowledge assert flag</p> <p>If the AA flag is set, an ACK (low level on I2C0_SDA) will be returned during the acknowledge clock pulse of the I2C0_SCL line while the I²C device is a receiver or an own-address-matching slave.</p> <p>If the AA flag is cleared, a NACK (high level on I2C0_SDA) will be returned during the acknowledge clock pulse of the I2C0_SCL line while the I²C device is a receiver or an own-address-matching slave. A device with its own AA flag cleared will ignore its own slave address and the General Call. Consequently, SI will not be asserted and no interrupt is requested.</p> <p>Note that if an addressed slave does not return an ACK under slave receiver mode or not receive an ACK under slave transmitter mode, the slave device will become a not addressed slave. It cannot receive any data until its AA flag is set and a master addresses it again.</p> <p>There is a special case of I2STAT value C8H occurs under slave transmitter mode. Before the slave device transmit the last data byte to the master, AA flag can be cleared as 0. Then after the last data byte transmitted, the slave device will actively switch to not addressed slave mode of disconnecting with the master. The further reading by the master will be all FFH.</p>
1	-	Reserved
0	I2CPX	<p>I2C pins select</p> <p>0 = Assign I2C0_SCL to P1.3 and I2C0_SDA to P1.4.</p> <p>1 = Assign I2C0_SCL to P0.2 and I2C0_SDA to P1.6.</p> <p>Note that I2C pins will exchange immediately once setting or clearing this bit.</p>

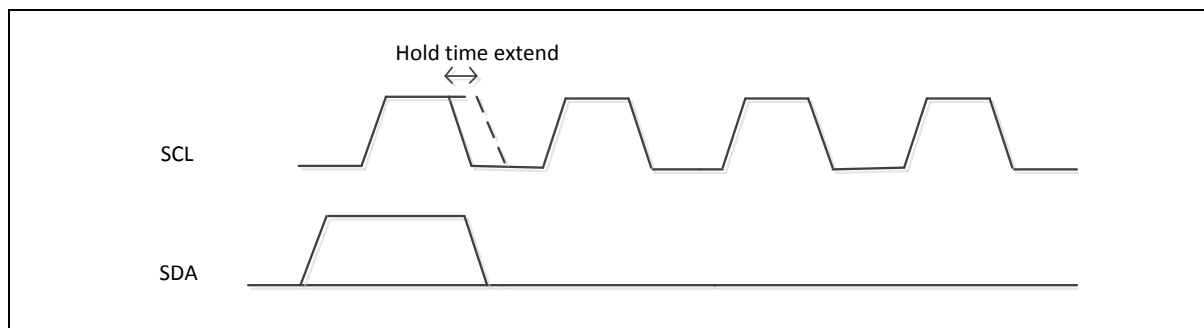

Figure 16.2-1 Hold Time extend enable

I2STAT – I²C Status

7	6	5	4	3	2	1	0
I2STAT[7:3]					0	0	0
R					R	R	R

Address: BDH Reset value: 1111 1000b

Bit	Name	Description
7:3	I2STAT[7:3]	I ² C status code The MSB five bits of I2STAT contains the status code. There are 27 possible status codes. When I2STAT is F8H, no relevant state information is available and SI flag keeps 0. All other 26 status codes correspond to the I ² C states. When each of these status is entered, SI will be set as logic 1 and a interrupt is requested.
2:0	0	Reserved The least significant three bits of I2STAT are always read as 0.

I2DAT – I²C Data

7	6	5	4	3	2	1	0
I2DAT[7:0]							
R/W							

Address: BCH Reset value: 0000 0000b

Bit	Name	Description
7:0	I2DAT[7:0]	I ² C data I2DAT contains a byte of the I ² C data to be transmitted or a byte, which has just received. Data in I2DAT remains as long as SI is logic 1. The result of reading or writing I2DAT during I ² C transceiving progress is unpredicted. While data in I2DAT is shifted out, data on the bus is simultaneously being shifted in to update I2DAT. I2DAT always shows the last byte that presented on the I ² C bus. Thus the event of lost arbitration, the original value of I2DAT changes after the transaction.

I²C Data Shifting Direction.

I2ADDR – I²C Own Slave Address

7	6	5	4	3	2	1	0
I2ADDR[7:1]							GC
R/W							R/W

Address: C1H Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:1	I2ADDR[7:1]	<p>I²C device's own slave address</p> <p><u>In master mode:</u></p> <p>These bits have no effect.</p> <p><u>In slave mode:</u></p> <p>These 7 bits define the slave address of this I²C device by user. The master should address I²C device by sending the same address in the first byte data after a START or a repeated START condition. If the AA flag is set, this I²C device will acknowledge the master after receiving its own address and become an addressed slave. Otherwise, the addressing from the master will be ignored.</p> <p>Note that I2ADDR[7:1] should not remain its default value of all 0, because address 0x00 is reserved for General Call.</p>
0	GC	<p>General Call bit</p> <p><u>In master mode:</u></p> <p>This bit has no effect.</p> <p><u>In slave mode:</u></p> <p>0 = The General Call is always ignored.</p> <p>1 = The General Call is recognized if AA flag is 1; otherwise, it is ignored if AA is 0.</p>

I2CLK – I²C Clock

7	6	5	4	3	2	1	0

R/W							

Address: BEH Reset value: 0000 1001b

Bit	Name	Description
7:0	I2CLK[7:0]	<p>I²C clock setting</p> <p><u>In master mode:</u></p> <p>This register determines the clock rate of I²C bus when the device is in a master mode. The clock rate follows the equation,</p> $\frac{F_{SYS}}{4 \times (I2CLK + 1)}$ <p>The default value will make the clock rate of I²C bus 400k bps if the peripheral clock is 16 MHz. Note that the I2CLK value of 00H and 01H are not valid. This is an implement limitation.</p> <p><u>In slave mode:</u></p> <p>This byte has no effect. In slave mode, the I²C device will automatically synchronize with any given clock rate up to 400k bps.</p>

16.3 Typical Structure of I²C Interrupt Service Routine

The following software example in C language for KEIL[™] C51 compiler shows the typical structure of the I²C interrupt service routine including the 26 state service routines and may be used as a base for user applications. User can follow or modify it for their own application. If one or more of the five

modes are not used, the associated state service routines may be removed, but care should be taken that a deleted routine can never be invoked.

```

Void I2C_ISR (void) interrupt 6
{
    switch (I2STAT)
    {
        //=====
        //Bus Error, always put in ISR for noise handling
        //=====
        case 0x00:                /*00H, bus error occurs*/
            STO = 1;              //recover from bus error
            break;

}

```

16.4 I2C Time-Out

There is a 14-bit time-out counter, which can be used to deal with the I²C bus hang-up. If the time-out counter is enabled, the counter starts up counting until it overflows. Meanwhile I2TOF will be set by hardware and requests I²C interrupt. When time-out counter is enabled, setting flag SI to high will reset counter and restart counting up after SI is cleared. If the I²C bus hangs up, it causes the SI flag not set for a period. The 14-bit time-out counter will overflow and require the interrupt service.

0	I2TOF	I ² C time-out flag This flag is set by hardware if 14-bit I ² C time-out counter overflows. It is cleared by software.

16.5 I²C Interrupt

There are two I²C flags, SI and I2TOF. Both of them can generate an I²C event interrupt requests. If I²C interrupt mask is enabled via setting EI2C and EA as 1, CPU will execute the I²C interrupt service routine once any of these two flags is set. User needs to check flags to determine what event caused the interrupt. Both of I²C flags are cleared by software.

17 PIN INTERRUPT

The MS51 provides pin interrupt input for each I/O pin to detect pin state if button or keypad set is used. A maximum 8-channel pin interrupt detection can be assigned by I/O port sharing. The pin interrupt is generated when any key is pressed on a keyboard or keypad, which produces an edge or level triggering event. Pin interrupt may be used to wake the CPU up from Idle or Power-down mode.

Each channel of pin interrupt can be enabled and polarity controlled independently by PIPEN and PINEN register. PICON selects which port that the pin interrupt is active. It also defines which type of pin interrupt is us— d – level detect or edge detect. Each channel also has its own interrupt flag. There are total eight pin interrupt flags located in PIF register. The respective flags for each pin interrupt channel allow the interrupt service routine to poll on which channel on which the interrupt event occurs. All flags in PIF register are set by hardware and should be cleared by software.

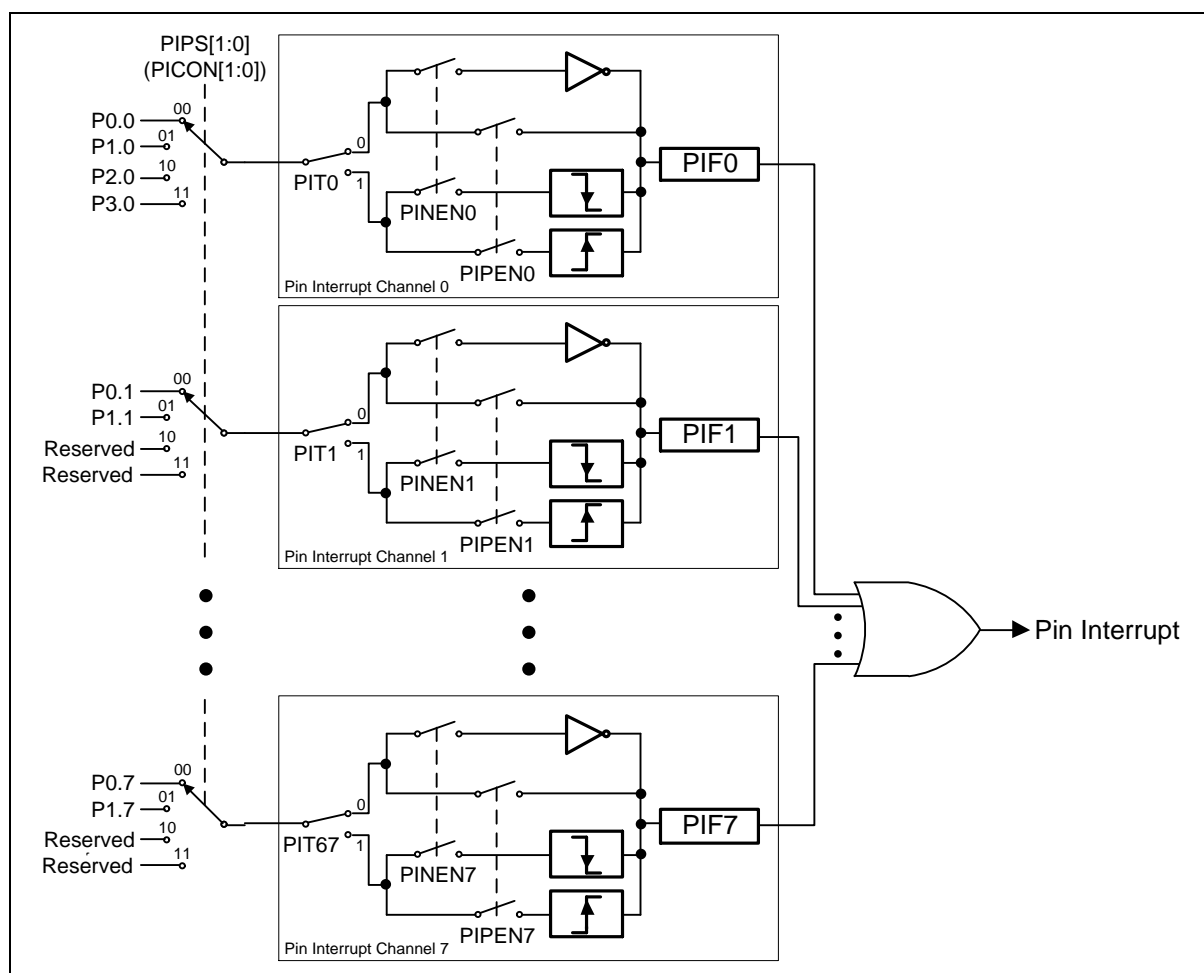

Figure 16.5-1 Pin Interface Block Diagram

Pin interrupt is generally used to detect an edge transient from peripheral devices like keyboard or keypad. During idle state, the system prefers to enter Power-down mode to minimize power consumption and waits for event trigger. Pin interrupt can wake up the device from Power-down mode.

18 PULSE WIDTH MODULATED (PWM)

The PWM (Pulse Width Modulation) signal is a useful control solution in wide application field. It can be used on motor driving, fan control, backlight brightness tuning, LED light dimming, or simulating as a simple digital to analog converter output through a low pass filter circuit.

The MS51 PWM is especially designed for motor control by providing three pairs, maximum 16-bit resolution of PWM output with programmable period and duty. The architecture makes user easy to drive the one-phase or three-phase brushless DC motor (BLDC), or three-phase AC induction motor. Each of six PWM can be configured as one of independent mode, complementary mode, or synchronous mode. If the complementary mode is used, a programmable dead-time insertion is available to protect MOS turn-on simultaneously. The PWM waveform can be edge-aligned or center-aligned with variable interrupt points.

18.1 Functional Description

18.1.1 PWM Generator

The PWM generator is clocked by the system clock or Timer 1 overflow divided by a PWM clock pre-scalar selectable from 1/1~1/128. The PWM period is defined by effective 16-bit period registers, {PWMnPH, PWMnPL}. The period is the same for all PWM channels for they share the same 16-bit period counter. The duty of each PWM is determined independently by the value of duty registers {PWMnC0H, PWMnC0L}, {PWMnC1H, PWMnC1L}, {PWMnC2H, PWMnC2L}, {PWMnC3H, PWMnC3L}, {PWMnC4H, PWMnC4L}, and {PWMnC5H, PWMnC5L}. With six duty registers, six PWM output can be generated independently with different duty cycles. The interval and duty of PWM signal is generated by a 16-bit counter comparing with the period and duty registers.

To facilitate the three-phase motor control, a group mode can be used by setting GP (PWMnCON1.5), which makes {PWMnC0H, PWMnC0L} and {PWMnC1H, PWMnC1L} duty register decide duties of the PWM outputs. In a three-phase motor control application, two-group PWM outputs generally are given the same duty cycle. When the group mode is enabled, {PWMnC2H, PWMnC2L}, {PWMnC3H, PWMnC3L}, {PWMnC4H, PWMnC4L} and {PWMnC5H, PWMnC5L} registers have no effect. This means {PWMnC2H, PWMnC2L} and {PWMnC4H, PWMnC4L} both are the same as {PWMnC0H, PWMnC0L}. Also {PWMnC3H, PWMnC3L} and {PWMnC5H, PWMnC5L} are the same as {PWMnC1H, PWMnC1L}. Note that enabling PWM does not configure the I/O pins into their output mode automatically. User should configure I/O output mode via software manually.

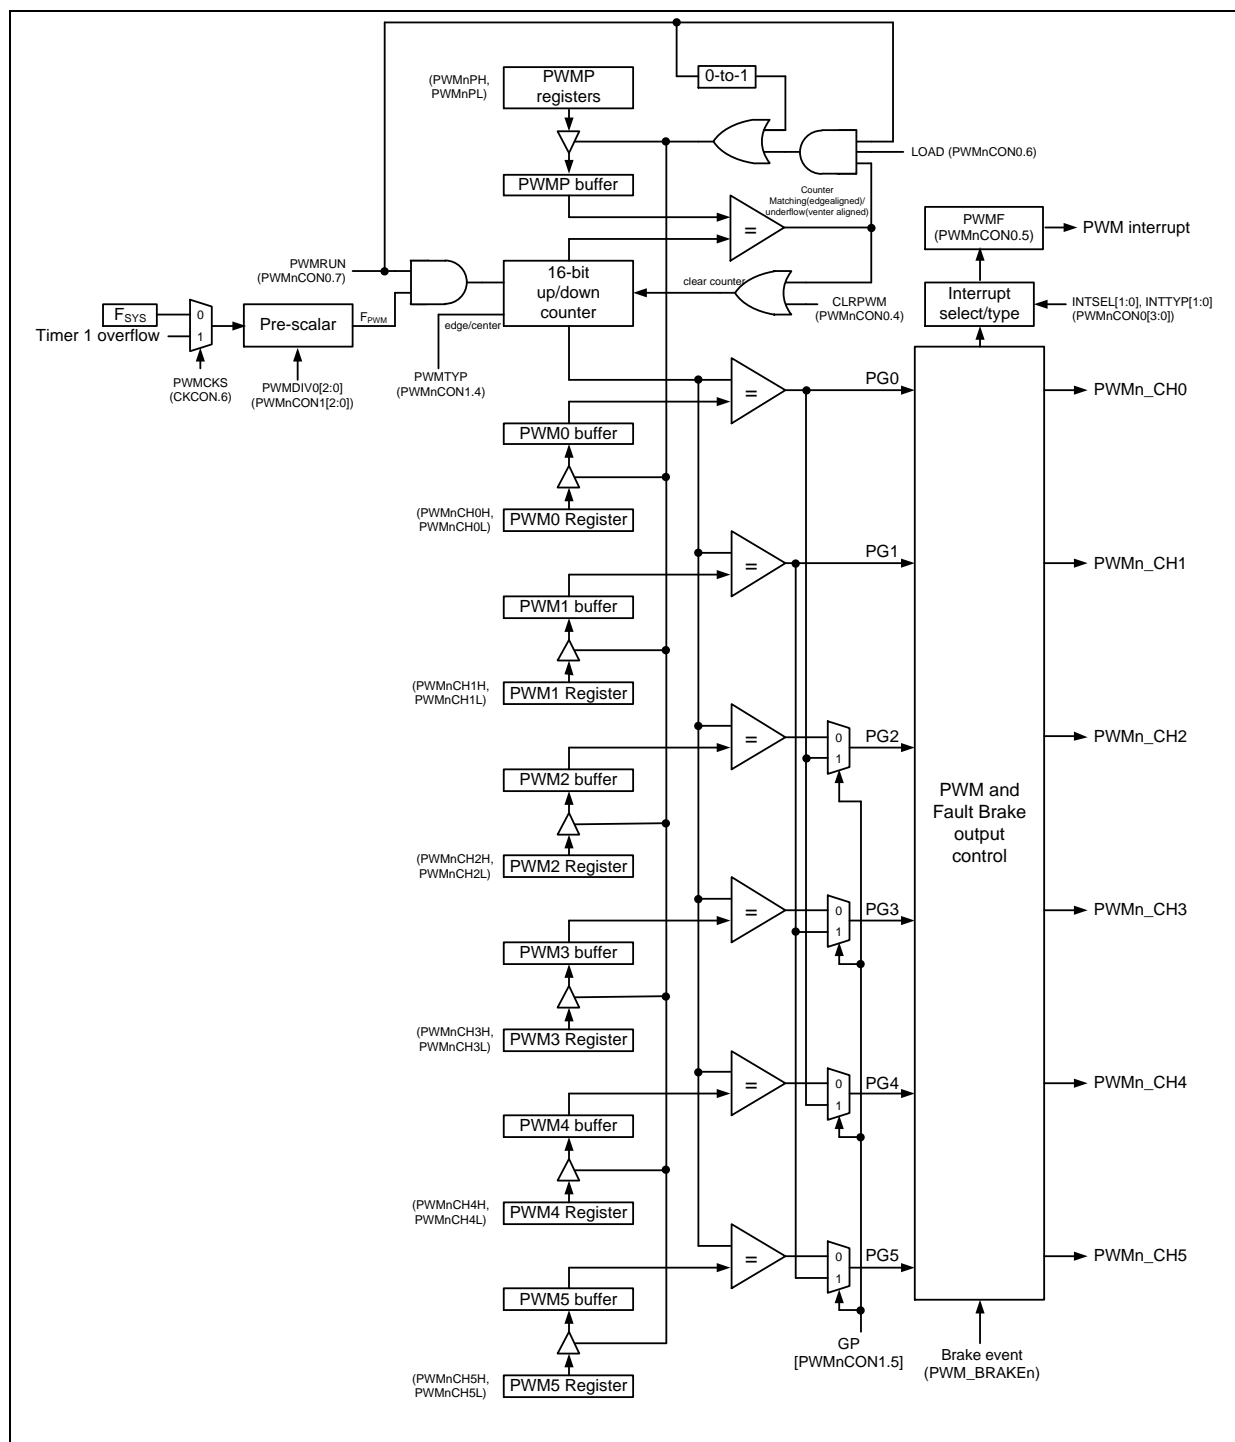

Figure 18.1-1 PWM Block Diagram

The PWM counter generates six PWM signals called PG0, PG1, PG2, PG3, PG4, and PG5. These signals will go through the PWM and Fault Brake output control circuit. It generates real PWM outputs on I/O pins. The output control circuit determines the PWM mode, dead-time insertion, mask output, Fault Brake control, and PWM polarity. The last stage is a multiplexer of PWM output or I/O function.

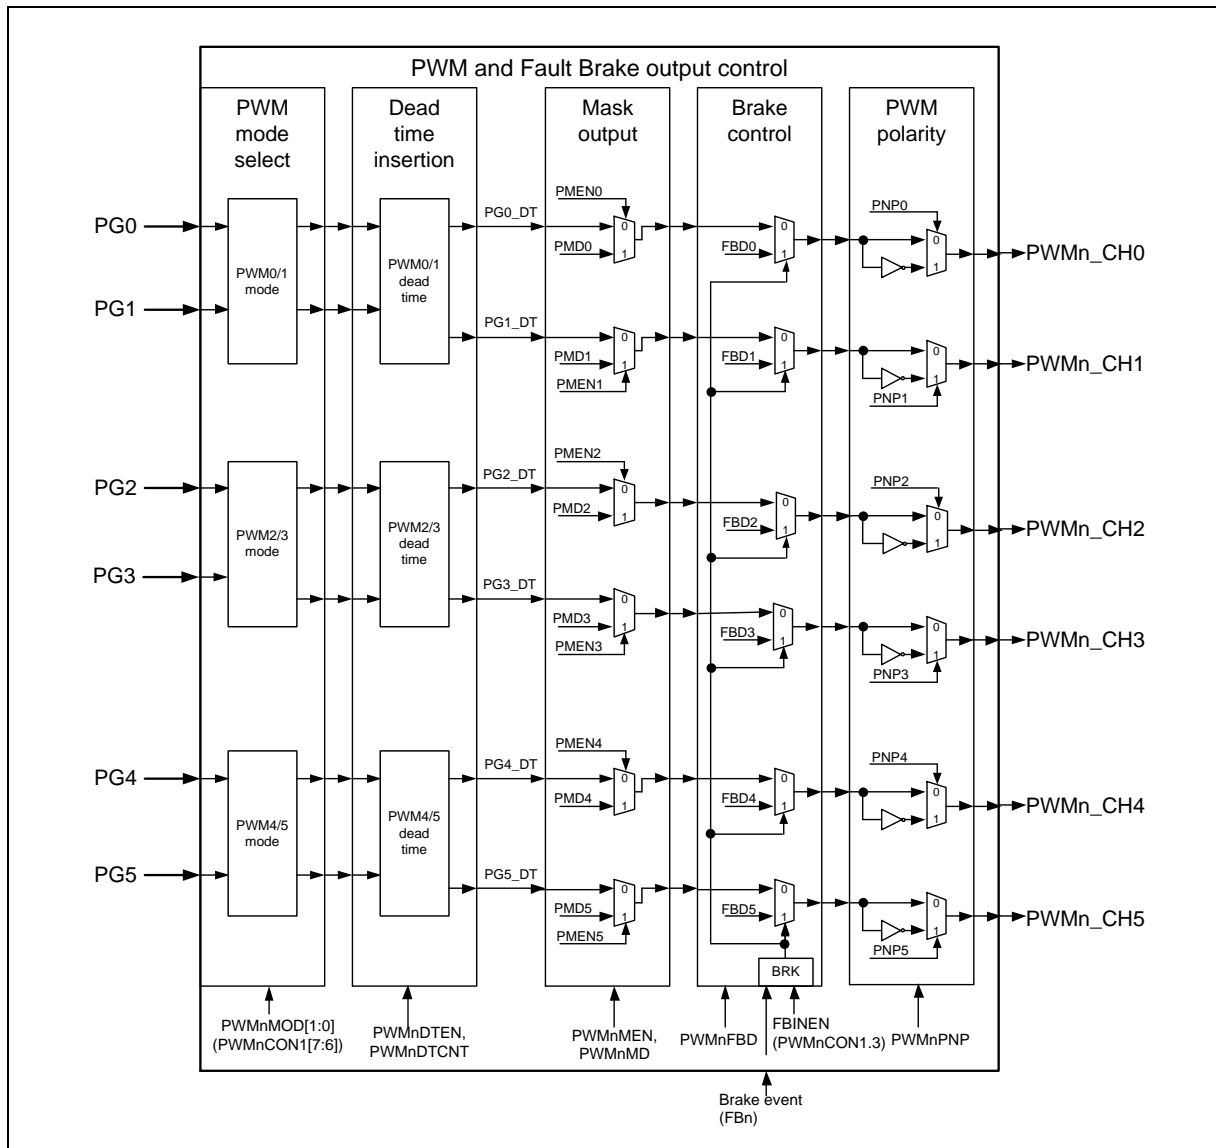

Figure 18.1-2 PWM and Fault Brake Output Control Block Diagram

User should follow the initialization steps below to start generating the PWM signal output. In the first step by setting CLRPWM (PWMnCON0.4), it ensures the 16-bit up counter reset for the accuracy of the first duration. After initialization and setting {PWMnPH, PWMnPL} and all {PWMnH, PWMnL} registers, PWMRUN (PWMnCON0.7) can be set as logic 1 to trigger the 16-bit counter running. PWM starts to generate waveform on its output pins. The hardware for all period and duty control registers are double buffered designed. Therefore, {PWMnPH, PWMnPL} and all {PWMnH, PWMnL} registers can be written to at any time, but the period and duty cycle of PWM will not be updated immediately until the LOAD (PWMnCON0.6) is set and previous period is complete. This prevents glitches when updating the PWM period or duty.

NOTE: A loading of new period and duty by setting LOAD should be ensured complete by monitoring it and waiting for a hardware automatic clearing LOAD bit. Any updating of PWM control registers during LOAD bit as logic 1 will cause unpredictable output.

PWMCON0 – PWM Control 0 (Bit-addressable)

7	6	5	4	3	2	1	0
PWMRUN	LOAD	PWMF	CLRPWM	-	-	-	-
R/W	R/W	R/W	R/W	-	-	-	-

18.1.2 PWM Types

The PWM generator provides two PWM types: edge-aligned or center-aligned. PWM type is selected by PWMTYP (PWMnCON1.4).

PWMCON1 – PWM Control 1

7	6	5	4	3	2	1	0
PWMMOD[1:0]		GP	PWMTYP	FBINEN	PWMDIV[2:0]		
R/W		R/W	R/W	R/W	R/W		

Address: DFH Reset value: 0000 0000b

Bit	Name	Description
4	PWMTYP	PWM type select 0 = Edge-aligned PWM. 1 = Center-aligned PWM.

18.1.2.1 Edge-Aligned Type

In edge-aligned mode, the 16-bit counter uses single slop operation by counting up from 0000H to {PWMnPH, PWMnPL} and then starting from 0000H. The PWM generator signal (PGn before PWM and Fault Brake output control) is cleared on the compare match of 16-bit counter and the duty register {PWMnH, PWMnL} and set at the 16-bit counter is 0000H. The result PWM output waveform is left-edge aligned.

Figure 18.1-3 PWM Edge-aligned Type Waveform

The output frequency and duty cycle for edge-aligned PWM are given by following equations:

PWM frequency = $\frac{F_{PWM}}{\{PWMnPH, PWMnPL\} + 1}$ (F_{PWM} is the PWM clock source frequency divided by PWMDIV).

PWM high level duty = $\frac{\{PWMnCHxH, PWMnCHxL\}}{\{PWMnPH, PWMnPL\} + 1}$.

18.1.2.2 Center-Aligned Type

In center-aligned mode, the 16-bit counter use dual slop operation by counting up from 0000H to {PWMnPH, PWMnPL} and then counting down from {PWMnPH, PWMnPL} to 0000H. The PGn signal is cleared on the up-count compare match of 16-bit counter and the duty register {PWMnH, PWMnL} and set on the down-count compare match. Center-aligned PWM may be used to generate non-overlapping waveforms.

Figure 18.1-4 PWM Center-aligned Type Waveform

The output frequency and duty cycle for center-aligned PWM are given by following equations:

PWM frequency = $\frac{F_{PWM}}{2 \times \{PWMnPH, PWMnPL\}}$ (F_{PWM} is the PWM clock source frequency divided by PWMDIV).

PWM high level duty = $\frac{\{PWMnCHxH, PWMnCHxL\}}{\{PWMnPH, PWMnPL\}}$.

18.1.3 Operation Modes

After PGN signals pass through the first stage of the PWM and Fault Brake output control circuit. The PWM mode selection circuit generates different kind of PWM output modes with six-channel, three-pair signal PG0~PG5 . It supports independent mode, complementary mode, and synchronous mode.

PWMCON1 – PWM Control 1

7	6	5	4	3	2	1	0

Bit	Name	Description
7:6	PWMMOD[1:0]	PWM mode select 00 = Independent mode. 01 = Complementary mode. 10 = Synchronized mode. 11 = Reserved.

18.1.3.1 Independent Mode

Independent mode is enabled when PWMMOD[1:0] (PWMnCON1[7:6]) is [0:0]. It is the default mode of PWM. PG0, PG1, PG2, PG3, PG4 and PG5 output PWM signals independently.

18.1.3.2 Complementary Mode with Dead-Time Insertion

Complementary mode is enabled when PWMMOD[1:0] = [0:1]. In this mode, PG0/2/4 output PWM signals the same as the independent mode. However, PG1/3/5 output the out-phase PWM signals of PG0/2/4 correspondingly, and ignore PG1/3/5 Duty register {PWMnH, PWMnL} (n:1/3/5). This mode makes PG0/PG1 a PWM complementary pair and so on PG2/PG3 and PG4/PG5.

In a real motor application, a complementary PWM output always has a need of “dead-time” insertion to prevent damage of the power switching device like GPIBs due to being active on simultaneously of the upper and lower switches of the half bridge, even in a “ μ s” duration. For a power switch device physically cannot switch on/off instantly. For the MS51 PWM, each PWM pair share a 9-bit dead-time down-counter PWM0DTCNT used to produce the off time between two PWM signals in the same pair. On implementation, a 0-to-1 signal edge delays after PWM0DTCNT timer underflows. The timing diagram illustrates the complementary mode with dead-time insertion of PG0/PG1 pair. Pairs of PG2/PG3 and PG4/PG5 have the same dead-time circuit. Each pair has its own dead-time enabling bit in the field of PWMnDTEN [3:0].

Note that the PWM0DTCNT and PWMnDTEN registers are all TA write protection. The dead-time control are also valid only when the PWM is configured in its complementary mode.

Figure 18.1-5 PWM Complementary Mode with Dead-time Insertion

Bit	Name	Description
7:0	PDTCNT[7:0]	PWM dead-time counter low byte This 8-bit field combined with PDTCNT.4 forms a 9-bit PWM dead-time counter PDTCNT. This counter is valid only when PWM is under complementary mode and the correspond PDTCNT bit for PWM pair is set. $\text{PWM dead-time} = \frac{\text{PDTCNT} + 1}{F_{\text{SYS}}}$ Note that user should not modify PDTCNT during PWM run time.

18.1.3.3 Synchronous Mode

Synchronous mode is enabled when PWMMOD[1:0] = [1:0]. In this mode, PG0/2/4 output PWM signals the same as the independent mode. PG1/3/5 output just the same in-phase PWM signals of PG0/2/4 correspondingly.

18.1.4 Mask Output Control

Each PWM signal can be software masked by driving a specified level of PWM signal. The PWM mask output function is quite useful when controlling Electrical Commutation Motor like a BLDC. PWMnMEN contains six bits, those determine which channel of PWM signal will be masked. PWMnMD set the individual mask level of each PWM channel. The default value of PWMnMEN is

00H, which makes all outputs of PWM channels follow signals from PWM generator. Note that the masked level is reversed or not by PWM0NP setting on PWM output pins.

PMEN – PWM Mask Enable

PMD – PWM Mask Data

7	6	5	4	3	2	1	0
-	-	PMD5	PMD4	PMD3	PMD2	PMD1	PMD0
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Address: FCH Reset value: 0000 0000b

Bit	Name	Description
n	PMDn	PWMn mask data The PWMn signal outputs mask data once its corresponding PMENn is set. 0 = PWMn signal is masked by 0. 1 = PWMn signal is masked by 1.

18.1.5 Fault Brake

The Fault Brake function is usually implemented in conjunction with an enhanced PWM circuit. It rules as a fault detection input to protect the motor system from damage. Fault Brake pin input (FB) is valid when FBINEN (PWMnCON1.3) is set. When Fault Brake is asserted PWM signals will be individually overwritten by PWMnFBD corresponding bits. PWMRUN (PWMnCON0.7) will also be automatically cleared by hardware to stop PWM generating. The PWM 16-bit counter will also be reset as 0000H. A indicating flag FBF will be set by hardware to assert a Fault Brake interrupt if enabled. PWMnFBD data output remains even after the FBF is cleared by software. User should resume the PWM output only by setting PWMRUN again. Meanwhile the Fault Brake state will be released and PWM waveform outputs on pins as usual. Fault Brake input has a polarity selection by FBINLS (PWMnFBD.6) bit. Note that the Fault Brake signal feed in FB pin should be longer than eight-system-clock time for FB pin input has a permanent $8/F_{SYS}$ de-bouncing, which avoids fake Fault Brake event by input noise. The other path to trigger a Fault Brake event is the ADC compare event. It asserts the Fault Brake behavior just the same as FB pin input. See Sector 19.1.3“ADC Conversion Result Comparator”.

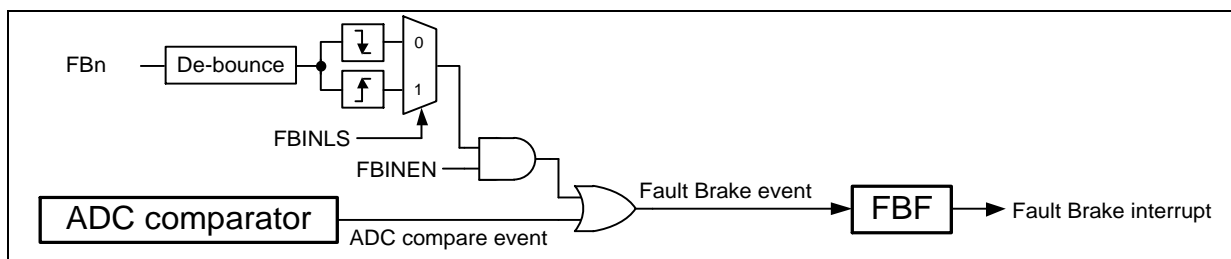

Figure 18.1-6 Fault Brake Function Block Diagram

PWMCON1 – PWM Control 1

FBF	FBINLS	FBD5	FBD4	FBD3	FBD2	FBD1	FBD0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: D7H Reset value: 0000 0000b

Bit	Name	Description
7	FBF	Fault Brake flag This flag is set when FBINEN is set as 1 and FB pin detects an edge, which matches FBINLS (FBD.6) selection. This bit is cleared by software. After FBF is cleared, Fault Brake data output will not be released until PWMRUN (PWMCON0.7) is set.
6	FBINLS	FB pin input level selection 0 = Falling edge. 1 = Rising edge.
N	FBDn	PWMn Fault Brake data 0 = PWMn signal is overwritten by 0 once Fault Brake asserted. 1 = PWMn signal is overwritten by 1 once Fault Brake asserted.

18.1.6 Polarity Control

Each PWM output channel has its independent polarity control bit, PNP0~PNP5. The default is high active level on all control fields implemented with positive logic. It means the power switch is ON when PWM outputs high level and OFF when low level. User can easily configure all setting with positive logic and then set PWMnNP bit to make PWM actually outputs according to the negative logic.

PNP – PWM Negative Polarity

7	6	5	4	3	2	1	0
-	-	PNP5	PNP4	PNP3	PNP2	PNP1	PNP0
-	-	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Name	Description
5:0	PNPn	PWMn negative polarity output enable 0 = PWMn signal outputs directly on PWMn pin. 1 = PWMn signal outputs inversely on PWMn pin.

18.2 PWM Interrupt

The PWM module has a flag PWMF (PWMnCON0.5) to indicate certain point of each complete PWM period. The indicating PWM channel and point can be selected by INTSEL[2:0] and INTTYP[1:0] (PWMnINTC[2:0] and [5:4]). Note that the center point and the end point interrupts are only available when PWM operates in its center-aligned type. PWMF is cleared by software.

PWMINTC – PWM Interrupt Control

-	-	INTTYP1	INTTYP0	-	INTSEL2	INTSEL1	INTSEL0
-	-	R/W	R/W	-	R/W	R/W	R/W

Address: B7H, Page:1 Reset value: 0000 0000b

Bit	Name	Description
5:4	INTTYP[1:0]	PWM interrupt type select These bit select PWM interrupt type. 00 = Falling edge on PWMn channel 0/1/2/3/4/5 pin. 01 = Rising edge on PWMn channel 0/1/2/3/4/5 pin. 10 = Central point of a PWM period. 11 = End point of a PWM period. Note that the central point interrupt or the end point interrupt is only available while PWM operates in center-aligned type.

Bit	Name	Description
2:0	INTSEL[2:0]	<p>PWM interrupt pair select</p> <p>These bits select which PWM channel asserts PWM interrupt when PWM interrupt type is selected as falling or rising edge on PWM0 channel 0~5 pin..</p> <p>000 = PWMn channel 0. 001 = PWMn channel1. 010 = PWMn channel2. 011 = PWMn channel3. 100 = PWMn channel4. 101 = PWMn channel5. Others = PWMn channel 0.</p>

The PWM interrupt related with PWM waveform is shown as figure below.

Figure 18.2-1 PWM Interrupt Type

Fault Brake event requests another interrupt, Fault Brake interrupt. It has different interrupt vector from PWM interrupt. When either Fault Brake pin input event or ADC compare event occurs, FBF (PWMnFBD.7) will be set by hardware. It generates Fault Brake interrupt if enabled. The Fault Brake interrupt enable bit is EFB0 (EIE0.5). FBF is cleared via software.

19 12-BIT ANALOG-TO-DIGITAL CONVERTER (ADC)

The MS51 is embedded with a 12-bit SAR ADC. The ADC (analog-to-digital converter) allows conversion of an analog input signal to a 12-bit binary representation of that signal. The MS51 is selected as 8-channel inputs in single end mode. The internal band-gap voltage 0.814 V also can be the internal ADC input. The analog input, multiplexed into one sample and hold circuit, charges a sample and hold capacitor. The output of the sample and hold capacitor is the input into the converter. The converter then generates a digital result of this analog level via successive approximation and stores the result in the result registers. The ADC controller also supports DMA (direct memory access) function for ADC continuous conversion and storage result data into XRAM no need special enable PDMA module.

19.1 Functional Description

19.1.1 ADC Operation

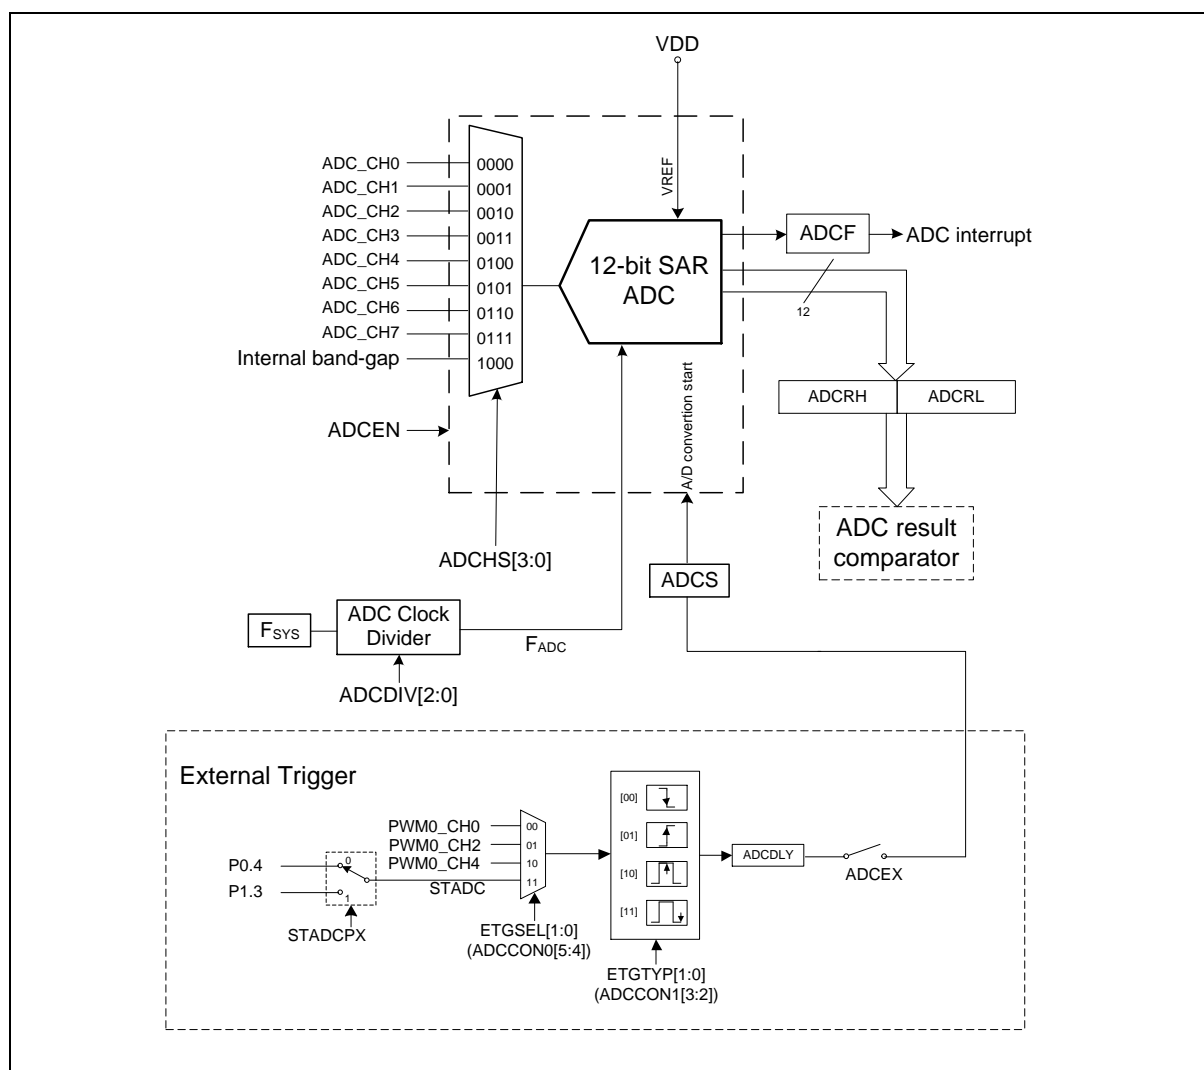

Figure 19.1-112-bit ADC Block Diagram

Before ADC operation, the ADC circuit should be enabled by setting ADCEN (ADCCON1.0). This makes ADC circuit active. It consume extra power. Once ADC is not used, clearing ADCEN to turn off ADC circuit saves power.

The ADC analog input pin should be specially considered. ADCHS[2:0] are channel selection bits that control which channel is connected to the sample and hold circuit. User needs to configure selected ADC input pins as input-only (high impedance) mode via respective bits in PxMn registers. This configuration disconnects the digital output circuit of each selected ADC input pin. But the digital input circuit still works. Digital input may cause the input buffer to induce leakage current. To disable the digital input buffer, the respective bits in AINDIDS should be set. Configuration above makes selected ADC analog input pins pure analog inputs to allow external feeding of the analog voltage signals. Also, the ADC clock rate needs to be considered carefully. The ADC maximum clock frequency is listed in ADC Analog Electrical Characteristics. Clock above the maximum clock frequency degrades ADC performance unpredictably.

An A/D conversion is initiated by setting the ADCS bit (ADCCON0.6). When the conversion is complete, the hardware will clear ADCS automatically, set ADCF (ADCCON0.7) and generate an interrupt if enabled. The new conversion result will also be stored in ADCRH (most significant 8 bits)

and ADCRL (least significant 4 bits). The 12-bit ADC result value is $4095 \times \frac{V_{AIN}}{V_{REF}}$.

By the way, digital circuitry inside and outside the device generates noise which might affect the accuracy of ADC measurements. If conversion accuracy is critical, the noise level can be reduced by applying the following techniques:

1. Keep analog signal paths as short as possible. Make sure to run analog signals tracks well away from high-speed digital tracks.
2. Place the device in Idle mode during a conversion.
3. If any ADC_CHn pins are used as digital outputs, it is essential that these do not switch while a conversion is in progress.

19.1.2 ADC Conversion Triggered by External Source

Besides setting ADCS via software, the MS51 is enhanced by supporting hardware triggering method to start an A/D conversion. If ADCEX (ADCCON1.1) is set, edges or period points on selected PWM channel or edges of STADC pin will automatically trigger an A/D conversion. (The hardware trigger also sets ADCS by hardware.)

The effective condition is selected by ETGSEL (ADCCON0[5:4]) and ETGTYP (ADCCON1[3:2]). A trigger delay can also be inserted between external trigger point and A/D conversion. The external

triggering ADC hardware with controllable trigger delay makes the MS51 feasible for high performance motor control. Note that during ADC is busy in converting ($ADCS = 1$), any conversion triggered by software or hardware will be ignored and there is no warning presented.

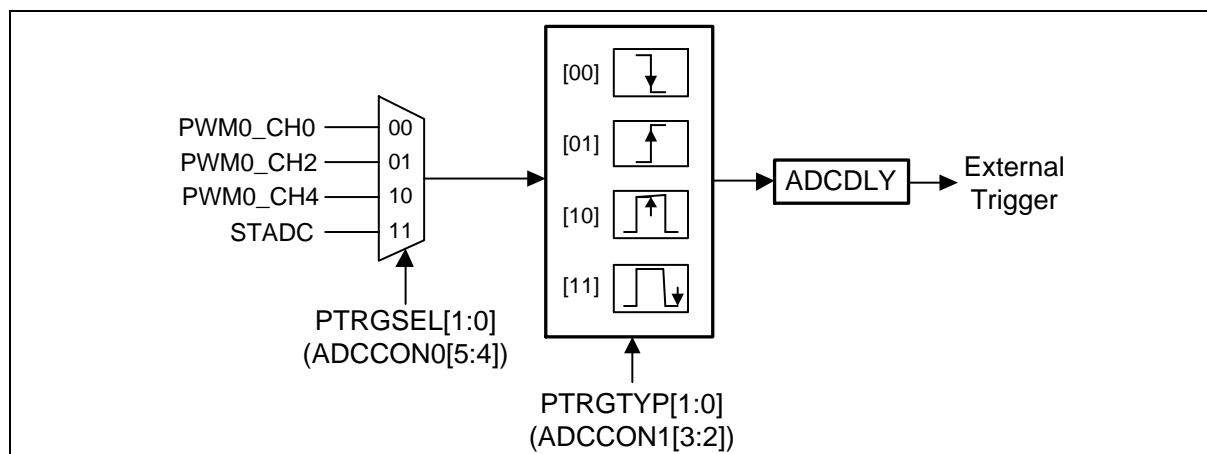

Figure 19.1-2 External Triggering ADC Circuit

19.1.3 ADC Conversion Result Comparator

The MS51 ADC has a digital comparator, which compares the A/D conversion result with a 12-bit constant value given in $ACMPH$ and $ACMPL$ registers. The ADC comparator is enabled by setting $ADCM PEN$ ($ADCCON2.5$) and each compare will be done on every A/D conversion complete moment. $ADCMPO$ ($ADCCON2.4$) shows the compare result according to its output polarity setting bit $ADCMPOP$ ($ADCCON2.6$). The ADC comparing result can trigger a PWM Fault Brake output directly. This function is enabled when $ADFBEN$ ($ADCCON2.7$). When $ADCMPO$ is set, it generates a ADC compare event and asserts Fault Brake. Please also see Sector 18.1.5“Fault Brake”.

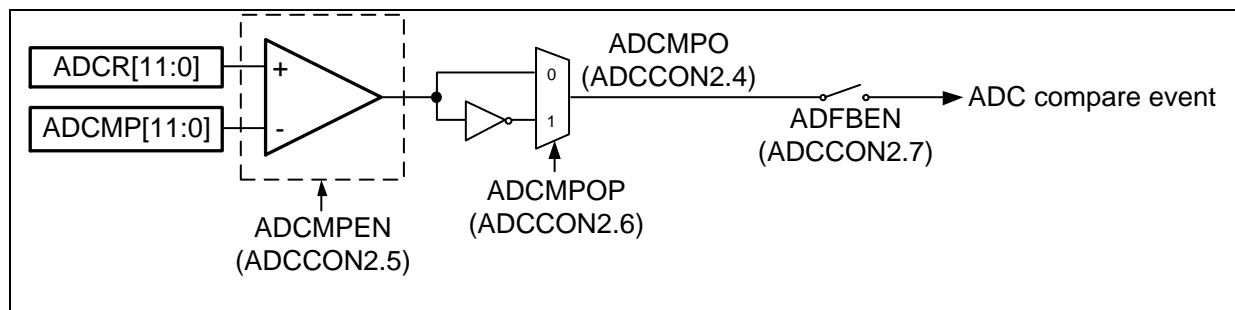

Figure 19.1-3 ADC Result Comparator

19.1.4 Internal Band-gap

At room temperature, all MS51 band-gap voltage values will be calibrated within the range of 1.17V to 1.30V. If you want to get the actual band-gap value for MS51, read the 2 bytes value after the UID address and the actually valid bit is 12. The first byte is the upper 8 bits, and the lower 4 bits of the second byte are the lower 4 bits of the 12 bit.

Reading and calculation steps:

1. Read a band-gap value with IAP by reading UID;
2. Merge the upper 8 bits and the lower 4 bits;
3. Use the following formula to convert to an actual voltage value.

Formula as following

$$\text{Bandgap_Voltage} = \frac{\text{Bandgap_Value} \times 3072}{4096} \text{ (mV)}$$

For example:

Read the 2 bytes value after the UID address, wherein the first byte value is 0x64, and the second byte value is 0x0E, merged as 0x64E = 1614. The conversion result is as follows:

$$\text{Bandgap_Voltage} = \frac{1614 \times 3072}{4096} = 1210.5 \text{ (mV)}$$

Band-gap as ADC input to calculate the V_{DD} value:

MS51 internal embedded band-gap voltage also can be the internal ADC input. This input is useful to measure Vref value then means can know the V_{DD} value from ADC convert result. For a more accuracy result when band-gap as ADC input, always give up the first three times convert data in register after ADC enable and suggest add 40us delay for a better result.

If ADCEN is 0, all inputs are disconnected.</p> <p>0000 = ADC_CH0.</p> <p>0001 = ADC_CH1.</p> <p>0010 = ADC_CH2.</p> <p>0011 = ADC_CH3.</p> <p>0100 = ADC_CH4.</p> <p>0101 = ADC_CH5.</p> <p>0110 = ADC_CH6.</p> <p>0111 = ADC_CH7</p> <p>1000 = Internal band-gap voltage.</p> <p>Others = Reserved.</p>

ADCCON1 – ADC Control 1

7	6	5	4	3	2	1	0
OCEN	STADCPX	ADCDIV[1:0]		ETGTYP[1:0]		ADCEX	ADCEN
R/W	R/W	R/W		R/W		R/W	R/W

Address: E1H Reset value: 0000 0000b

Bit	Name	Description
6	STADCPX	<p>External start ADC trigger pin select</p> <p>0 = Assign STADC to P0.4.</p> <p>1 = Assign STADC to P1.3.</p> <p>Note that STADC will exchange immediately once setting or clearing this bit.</p>

Bit	Name	Description
5:4	ADCDIV[1:0]	ADC clock divider 00 = ADC clock source = $F_{SYS}/1$. 01 = ADC clock source = $F_{SYS}/2$. 10 = ADC clock source = $F_{SYS}/4$. 11 = ADC clock source = $F_{SYS}/8$.
3:2	ETGTYP[1:0]	External trigger type select When ADCEX (ADCCON1.1) is set, these bits select which condition triggers ADC conversion. 00 = Falling edge on PWM0 channel 0/2/4 or STADC pin. 01 = Rising edge on PWM0 channel 0/2/4 or STADC pin. 10 = Central point of a PWM0 period. 11 = End point of a PWM0 period. Note that the central point interrupt or the period point interrupt is only available for PWM center-aligned type.
1	ADCEX	ADC external conversion trigger select This bit select the methods of triggering an A/D conversion. 0 = A/D conversion is started only via setting ADCS bit. 1 = A/D conversion is started via setting ADCS bit or by external trigger source depending on ETGSEL[1:0] and ETGTYP[1:0]. Note that while ADCS is 1 (busy in converting), the ADC will ignore the following external trigger until ADCS is hardware cleared.
0	ADCEN	ADC enable 0 = ADC circuit off. 1 = ADC circuit on.

ADCCON2 – ADC Control 2

7	6	5	4	3	2	1	0
ADFBEN	ADCMPOP	ADCMPEN	ADCMPO	ADCAQT[2:0]			ADCDLY.8
R/W	R/W	R/W	R	R/W			R/W

Address: E2H Reset value: 0000 0000b

Bit	Name	Description
7	ADFBEN	ADC compare result asserting Fault Brake enable 0 = ADC asserting Fault Brake Disabled. 1 = ADC asserting Fault Brake Enabled. Fault Brake is asserted once its compare result ADCMPO is 1. Meanwhile, PWM channels output Fault Brake data. PWMRUN (PWMCON0.7) will also be automatically cleared by hardware. The PWM output resumes when PWMRUN is set again.
6	ADCMPOP	ADC comparator output polarity 0 = ADCMPO is 1 if ADCR[11:0] is greater than or equal to ADCMP[11:0]. 1 = ADCMPO is 1 if ADCR[11:0] is less than ADCMP[11:0].

Bit	Name	Description
5	ADCMPE	ADC result comparator enable 0 = ADC result comparator Disabled. 1 = ADC result comparator Enabled.
4	ADCMPO	ADC comparator output value This bit is the output value of ADC result comparator based on the setting of ACMPOP. This bit updates after every A/D conversion complete.
3:1	ADCAQT	ADC acquisition time This 3-bit field decides the acquisition time for ADC sampling, following by equation below: $\text{ADC acquisition time} = \frac{4 * \text{ADCAQT} + 6}{F_{\text{ADC}}}$ The default and minimum acquisition time is 6 ADC clock cycles. Note that this field should not be changed when ADC is in converting.
0	ADCDLY.8	ADC external trigger delay counter bit 8 See ADCDLY register.

AINDIDS – ADC Channel Digital Input Disconnect

7	6	5	4	3	2	1	0
P11DIDS	P03DIDS	P04DIDS	P05DIDS	P06DIDS	P07DIDS	P30DIDS	P17DIDS
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F6H Reset value: 0000 0000b

Bit	Name	Description
n	AINnDIDS	ADC Channel digital input disable 0 = ADC channel n digital input Enabled. 1 = ADC channel n digital input Disabled. ADC channel n is read always 0.

ADCDLY – ADC Trigger Delay Counter

7	6	5	4	3	2	1	0
ADCDLY[7:0]							
R/W							

Address: E3H Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCDLY[7:0]	ADC external trigger delay counter low byte This 8-bit field combined with ADCCON2.0 forms a 9-bit counter. This counter inserts a delay after detecting the external trigger. An A/D converting starts after this period of delay. $\text{External trigger delay time} = \frac{\text{ADCDLY}}{F_{\text{ADC}}}$ Note that this field is valid only when ADCEX (ADCCON1.1) is set. User should not modify ADCDLY during PWM run time if selecting PWM output as the external ADC trigger source.

ADCRH – ADC Result High Byte

7	6	5	4	3	2	1	0
ADCR[11:4]							
R							

Address: C3H Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCR[11:4]	ADC result high byte The most significant 8 bits of the ADC result stored in this register.

ADCRL – ADC Result Low Byte

7	6	5	4	3	2	1	0
-	-	-	-	ADCR[3:0]			
-	-	-	-	R			

Address: C2H Reset value: 0000 0000b

Bit	Name	Description
3:0	ADCR[3:0]	ADC result low byte The least significant 4 bits of the ADC result stored in this register.

ADCMPH – ADC Compare High Byte

7	6	5	4	3	2	1	0
ADCMP[11:4]							
W/R							

Address: CFH Reset value: 0000 0000b

Bit	Name	Description
7:0	ADCMP[11:4]	ADC compare high byte The most significant 8 bits of the ADC compare value stores in this register.

ADCMPL – ADC Compare Low Byte

7	6	5	4	3	2	1	0
-	-	-	-	ADCMP[3:0]			
-	-	-	-	W/R			

Address: CEH Reset value: 0000 0000b

Bit	Name	Description
3:0	ADCMP[3:0]	ADC compare low byte The least significant 4 bits of the ADC compare value stores in this register.

AUXR1 – Auxiliary Register 1

7	6	5	4	3	2	1	0
SWRF	RSTPINF	HardF	SLOW	GF2	UART0PX	0	DPS
R/W	R/W	R/W	R/W	R/W	R/W	R	R/W

Address: A2H Reset value: POR 0000 0000b, Software 1U00 0000b, nRESET pin U100 0000b, Others UUU0 0000b

Bit	Name	Description
4	SLOW	<p>ADC Slow Speed Selection</p> <p>This bit is used to select ADC low speed.</p> <p>0 = high speed 500 ksps</p> <p>1 = low speed 200 ksps</p>

20 TIMED ACCESS PROTECTION (TA)

The MS51 has several features such as WDT and Brown-out detection that are crucial to proper operation of the system. If leaving these control registers unprotected, errant code may write undetermined value into them and results in incorrect operation and loss of control. To prevent this risk, the MS51 has a protection scheme, which limits the write access to critical SFR. This protection scheme is implemented using a timed access (TA). The following registers are related to the TA process.

TA – Timed Access

7	6	5	4	3	2	1	0
TA[7:0]							
W							

Address: C7H, All pages Reset value: 0000 0000b

Bit	Name	Description
7:0	TA[7:0]	<p>Timed access</p> <p>The timed access register controls the access to protected SFR. To access protected bits, user should first write AAH to the TA and immediately followed by a write of 55H to TA. After these two steps, a writing permission window is opened for 4 clock cycles during this period that user may write to protected SFR.</p>

In timed access method, the bits, which are protected, have a timed write enable window. A write is successful only if this window is active, otherwise the write will be discarded. When the software writes AAH to TA, a counter is started. This counter waits for 3 clock cycles looking for a write of 55H to TA. If the second write of 55H occurs within 3 clock cycles of the first write of AAH, then the timed access window is opened. It remains open for 4 clock cycles during which user may write to the protected bits. After 4 clock cycles, this window automatically closes. Once the window closes, the procedure should be repeated to write another protected bits. Not that the TA protected SFR are required timed access for writing but reading is not protected. User may read TA protected SFR without giving AAH and 55H to TA register. The suggestion code for opening the timed access window is shown below.

```

(CLR EA)                ;if any interrupt is enabled, disable temporally
MOV  TA, #0AAH
MOV  TA, #55H
(Instruction that writes a TA protected register)
(SETBEA)                 ;resume interrupts enabled
    
```

Any enabled interrupt should be disabled during this procedure to avoid delay between these three writings. If there is no interrupt enabled, the CLR EA and SETB EA instructions can be left out.

Examples of timed access are shown to illustrate correct or incorrect writing process.

Example 1,

```
MOV  TA, #0AAH      ;3 clock cycles
MOV  TA, #55H        ;3 clock cycles
ORL  WDCON, #data    ;4 clock cycles
```

Example 2,

```
MOV  TA, #0AAH      ;3 clock cycles
MOV  TA, #55H        ;3 clock cycles
NOP                      ;1 clock cycle
ANL  BODCON0, #data  ;4 clock cycles
```

Example 3,

```
MOV  TA, #0AAH      ;3 clock cycles
MOV  TA, #55H        ;3 clock cycles
MOV  WDCON, #data1    ;3 clock cycles
ORL  BODCON0, #data2 ;4 clock cycles
```

Example 4,

```
MOV  TA, #0AAH      ;3 clock cycles
NOP                      ;1 clock cycle
MOV  TA, #55H        ;3 clock cycles
ANL  BODCON0, #data  ;4 clock cycles
```

In the first example, the writing to the protected bits is done before the 3-clock-cycle window closes. In example 2, however, the writing to BODCON0 does not complete during the window opening, there will be no change of the value of BODCON0. In example 3, the WDCON is successful written but the BODCON0 write is out of the 3-clock-cycle window. Therefore, the BODCON0 value will not change either. In Example 4, the second write 55H to TA completes after 3 clock cycles of the first write TA of AAH, and thus the timed access window is not opened at all, and the write to the protected byte affects nothing.

21 INTERRUPT SYSTEM

21.1 Interrupt Overview

The purpose of the interrupt is to make the software deal with unscheduled or asynchronous events. The MS51 has a four-priority-level interrupt structure with 30 interrupt sources. Each of the interrupt sources has an individual priority setting bits, interrupt vector and enable bit. In addition, the interrupts can be globally enabled or disabled. When an interrupt occurs, the CPU is expected to service the interrupt. This service is specified as an Interrupt Service Routine (ISR). The ISR resides at a predetermined address as shown in Table 21.1-1 Interrupt Vectors. When the interrupt occurs if enabled, the CPU will vector to the respective location depending on interrupt source, execute the code at this location, stay in an interrupt service state until the ISR is done. Once an ISR has begun, it can be interrupted only by a higher priority interrupt. The ISR should be terminated by a return from interrupt instruction RETI. This instruction will force the CPU return to the instruction that would have been next when the interrupt occurred.

Source	Vector Address	Vector Number	Source	Vector Address	Vector Number
Reset	0000H	-	SPI interrupt	004BH	9
External interrupt 0	0003H	0	WDT interrupt	0053H	10
Timer 0 overflow	000BH	1	ADC interrupt	005BH	11
External interrupt 1	0013H	2	Input capture interrupt	0063H	12
Timer 1 overflow	001BH	3	PWM interrupt	006BH	13
Serial port 0 interrupt	0023H	4	Fault Brake interrupt	0073H	14
Timer 2 event	002BH	5	Serial port 1 interrupt	007BH	15
I ² C status/timer-out interrupt	0033H	6	Timer 3 overflow	0083H	16
Pin interrupt	003BH	7	Self Wake-up Timer interrupt	008BH	17
Brown-out detection interrupt	0043H	8			

Table 21.1-1 Interrupt Vectors

21.2 Enabling Interrupts

Each of individual interrupt sources can be enabled or disabled through the use of an associated interrupt enable bit in the IE and EIE0 SFR. There is also a global enable bit EA bit (IE.7), which can be cleared to disable all the interrupts at once. It is set to enable all individually enabled interrupts. Setting the EA bit to logic 0 disables all interrupt sources regardless of the individual interrupt-enable

settings. Note that interrupts which occur when the EA bit is set to logic 0 will be held in a pending state, and will not be serviced until the EA bit is set back to logic 1. All interrupt flags that generate interrupts can also be set via software. Thereby software initiated interrupts can be generated.

Note that every interrupts, if enabled, is generated by a setting as logic 1 of its interrupt flag no matter by hardware or software. User should take care of each interrupt flag in its own interrupt service routine (ISR). Most of interrupt flags should be cleared by writing it as logic 0 via software to avoid recursive interrupt requests.

IE – Interrupt Enable (Bit-addressable)

7	6	5	4	3	2	1	0
EA	EADC	EBOD	ES	ET1	EX1	ET0	EX0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: A8H Reset value: 0000 0000b

Bit	Name	Description
7	EA	Enable all interrupt This bit globally enables/disables all interrupts that are individually enabled. 0 = All interrupt sources Disabled. 1 = Each interrupt Enabled depending on its individual mask setting. Individual interrupts will occur if enabled.
6	EADC	Enable ADC interrupt 0 = ADC interrupt Disabled. 1 = Interrupt generated by ADCF (ADCCON0.7) Enabled.
5	EBOD	Enable brown-out interrupt 0 = Brown-out detection interrupt Disabled. 1 = Interrupt generated by BOF (BODCON0.3) Enabled.
4	ES	Enable serial port 0 interrupt 0 = Serial port 0 interrupt Disabled. 1 = Interrupt generated by TI (SCON.1) or RI (SCON.0) Enabled.
3	ET1	Enable Timer 1 interrupt 0 = Timer 1 interrupt Disabled. 1 = Interrupt generated by TF1 (TCON.7) Enabled.
2	EX1	Enable external interrupt 1 0 = External interrupt 1 Disabled. 1 = Interrupt generated by $\overline{\text{INT}}1$ pin (P1.7) Enabled.
1	ET0	Enable Timer 0 interrupt 0 = Timer 0 interrupt Disabled. 1 = Interrupt generated by TF0 (TCON.5) Enabled.

Bit	Name	Description
0	EX0	Enable external interrupt 0 0 = External interrupt 0 Disabled. 1 = Interrupt generated by $\overline{\text{INT0}}$ pin (P3.0) Enabled.

EIE – Extensive Interrupt Enable

7	6	5	4	3	2	1	0
ET2	ESPI	EFB	EWDT	EPWM	ECAP	EPI	EI2C
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: 9BH Reset value: 0000 0000b

Bit	Name	Description
7	ET2	Enable Timer 2 interrupt 0 = Timer 2 interrupt Disabled. 1 = Interrupt generated by TF2 (T2CON.7) Enabled.
6	ESPI	Enable SPI interrupt 0 = SPI interrupt Disabled. 1 = Interrupt generated by SPIF (SPSR.7), SPIOVF (SPSR.5), or MODF (SPSR.4) Enable.
5	EFB	Enable Fault Brake interrupt 0 = Fault Brake interrupt Disabled. 1 = Interrupt generated by FBF (FBD.7) Enabled.
4	EWDT	Enable WDT interrupt 0 = WDT interrupt Disabled. 1 = Interrupt generated by WDTF (WDCON.5) Enabled.
3	EPWM	Enable PWM interrupt 0 = PWM interrupt Disabled. 1 = Interrupt generated by PWMF (PWMCON0.5) Enabled.
2	ECAP	Enable input capture interrupt 0 = Input capture interrupt Disabled. 1 = Interrupt generated by any flags of CAPF[2:0] (CAPCON0[2:0]) Enabled.
1	EPI	Enable pin interrupt 0 = Pin interrupt Disabled. 1 = Interrupt generated by any flags in PIF register Enabled.
0	EI2C	Enable I ² C interrupt 0 = I ² C interrupt Disabled. 1 = Interrupt generated by SI (I2CON.3) or I2TOF (I2TOC.0) Enabled.

EIE1 – Extensive Interrupt Enable 1

7	6	5	4	3	2	1	0
---	---	---	---	---	---	---	---

-	-	-	-	-	EWKT	ET3	ES_1
-	-	-	-	-	R/W	R/W	R/W

Address: 9CH Reset value: 0000 0000b

Bit	Name	Description
2	EWKT	Enable WKT interrupt 0 = WKT interrupt Disabled. 1 = Interrupt generated by WKTF (WKCON.4) Enabled.
1	ET3	Enable Timer 3 interrupt 0 = Timer 3 interrupt Disabled. 1 = Interrupt generated by TF3 (T3CON.4) Enabled.
0	ES_1	Enable serial port 1 interrupt 0 = Serial port 1 interrupt Disabled. 1 = Interrupt generated by TI_1 (SCON_1.1) or RI_1 (SCON_1.0) Enabled.

21.3 Interrupt Priorities

There are four priority levels for all interrupts. They are level highest, high, low, and lowest; and they are represented by level 3, level 2, level 1, and level 0. The interrupt sources can be individually set to one of four priority levels by setting their own priority bits. [Table 21.3-1](#) lists four priority setting. Naturally, a low level priority interrupt can itself be interrupted by a high level priority interrupt, but not by any same level interrupt or lower level. In addition, there exists a pre-defined natural priority among the interrupts themselves. The natural priority comes into play when the interrupt controller has to resolve simultaneous requests having the same priority level.

In case of multiple interrupts, the following rules apply:

1. While a low priority interrupt handler is running, if a high priority interrupt arrives, the handler will be interrupted and the high priority handler will run. When the high priority handler does “RETI”, the low priority handler will resume. When this handler does “RETI”, control is passed back to the main program.
2. If a high priority interrupt is running, it cannot be interrupted by any other source – even if it is a high priority interrupt which is higher in natural priority.
3. A low-priority interrupt handler will be invoked only if no other interrupt is already executing. Again, the low priority interrupt cannot preempt another low priority interrupt, even if the later one is higher in natural priority.
4. If two interrupts occur at the same time, the interrupt with higher priority will execute first. If both interrupts are of the same priority, the interrupt which is higher in natural priority will be executed first. This is the only context in which the natural priority matters.

This natural priority is defined as shown on [Table 21.3-1 Interrupt Priority Level Setting](#)

. It also summarizes the interrupt sources, flag bits, vector addresses, enable bits, priority bits, natural priority and the permission to wake up the CPU from Power-down mode. For details of waking CPU up from Power-down mode, please see [Section 23.2 “Power-Down Mode”](#)

Interrupt Priority Control Bits		Interrupt Priority Level
IPH / EIPH / EIPH1	IP / EIP / EIP2	
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

Table 21.3-1 Interrupt Priority Level Setting

Interrupt Source	Vector Address	Interrupt Flag(S)	Enable Bit	Natural Priority	Priority Control Bits	Power-Down Wake-Up
Reset	0000H	-	Always Enabled	Highest	-	Yes
External interrupt 0	0003H	IE0[1]	EX0	1	PX0, PX0H	Yes
Brown-out	0043H	BOF (BODCON0.3)	EBOD	2	PBOD, PBODH	Yes
Watchdog Timer	0053H	WDTF (WDCON.5)	EWDT	3	PWDT, PWDTH	Yes
Timer 0	000BH	TF0[2]	ET0	4	PT0, PT0H	No
I2C status/time-out	0033h	SI + I2TOF (I2TOC.0)	EI2C	5	PI2C, PI2CH	No
ADC	005Bh	ADCF	EADC	6	PADC, PADCH	No
External interrupt 1	0013H	IE1[1]	EX1	7	PX1, PX1H	Yes
Pin interrupt	003BH	PIF0 to PIF7 (PIF)[3]	EPI	8	PPI, PPIH	Yes
Timer 1	001BH	TF1[2]	ET1	9	PT1, PT1H	No
Serial port 0	0023H	RI + TI	ES	10	PS, PSH	No
Fault Brake event	0073h	FBF (FBD.7)	EFB	11	PFB, PFBH	No
SPI	004Bh	SPIF (SPSR.7) + MODF (SPSR.4) + SPIOVF (SPSR.5)	ESPI	12	PSPI, PSPIH	No
Timer 2	002BH	TF2[2]	ET2	13	PT2, PT2H	No
Input capture	0063H	CAPF[2:0] (CAPCON0[2:0])	ECAP	14	PCAP, PCAPH	No
PWM interrupt	006BH	PWMF	EPWM	15	PPWM, PPWMH	No
Serial port 1	007BH	RI_1 + TI_1	ES_1	16	PS_1, PSH_1	No
Timer 3	0083H	TF3[2] (T3CON.4)	ET3	17	PT3, PT3H	No
Self Wake-up Timer	008BH	WKTF (WKCON.4)	EWKT	18	PWKT, PWKTH	Yes
Note: 1. While the external interrupt pin is set as edge triggered (Itx = 1), its own flag lex will be automatically cleared if the interrupt service routine (ISR) is executed. While as level triggered (Itx = 0), lex follows the inverse of respective pin state. It is not controlled via software. 2. TF0, TF1, or TF3 is automatically cleared if the interrupt service routine (ISR) is executed. On the contrary, be aware that TF2 is not. 3. If level triggered is selected for pin interrupt channel n, PIFn flag reflects the respective channel state. It is not controlled via software.						

Table 21.3-2 Characteristics of Each Interrupt Source

IP – Interrupt Priority (Bit-addressable)

7	6	5	4	3	2	1	0
-	PADC	PBOD	PS	PT1	PX1	PT0	PX0
-	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B8H Reset value: 0000 0000b

Bit	Name	Description
6	PADC	ADC interrupt priority low bit
5	PBOD	Brown-out detection interrupt priority low bit
4	PS	Serial port 0 interrupt priority low bit
3	PT1	Timer 1 interrupt priority low bit
2	PX1	External interrupt 1 priority low bit
1	PT0	Timer 0 interrupt priority low bit
0	PX0	External interrupt 0 priority low bit

Note: IP is used in combination with the IPH to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

IPH – Interrupt Priority High

7	6	5	4	3	2	1	0
-	PADCH	PBODH	PSH	PT1H	PX1H	PT0H	PX0H
-	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: B7H, Page0 Reset value: 0000 0000b

Bit	Name	Description
6	PADC	ADC interrupt priority high bit
5	PBOD	Brown-out detection interrupt priority high bit
4	PSH	Serial port 0 interrupt priority high bit
3	PT1H	Timer 1 interrupt priority high bit
2	PX1H	External interrupt 1 priority high bit
1	PT0H	Timer 0 interrupt priority high bit
0	PX0H	External interrupt 0 priority high bit

Note: IPH is used in combination with the IP respectively to determine the priority of each interrupt source. See [Table 21.3-1 Interrupt Priority Level Setting](#) for correct interrupt priority configuration.

EIP – Extensive Interrupt Priority

7	6	5	4	3	2	1	0
PT2	PSPI	PFB	PWDT	PPWM	PCAP	PPI	PI2C
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: EFH Reset value: 0000 0000b

Bit	Name	Description
7	PT2	Timer 2 interrupt priority low bit
6	PSPI	SPI interrupt priority low bit
5	PFB	Fault Brake interrupt priority low bit
4	PWDT	WDT interrupt priority low bit
3	PPWM	PWM interrupt priority low bit
2	PCAP	Input capture interrupt priority low bit
1	PPI	Pin interrupt priority low bit
0	PI2C	I ² C interrupt priority low bit

Note : EIP is used in combination with the EIPH to determine the priority of each interrupt source. See Table 21.3-1 Interrupt Priority Level Setting for correct interrupt priority configuration.

EIPH – Extensive Interrupt Priority High^[4]

7	6	5	4	3	2	1	0
PT2H	PSPIH	PFBH	PWDTH	PPWMH	PCAPH	PPIH	PI2CH
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Address: F7H Reset value: 0000 0000b

Bit	Name	Description
7	PT2H	Timer 2 interrupt priority high bit
6	PSPIH	SPI interrupt priority high bit
5	PFBH	Fault Brake interrupt priority high bit
4	PWDTH	WDT interrupt priority high bit
3	PPWMH	PWM interrupt priority high bit
2	PCAPH	Input capture interrupt priority high bit
1	PPIH	Pin interrupt priority high bit
0	PI2CH	I ² C interrupt priority high bit

Bit	Name	Description
Note : EIPH is used in combination with the EIP to determine the priority of each interrupt source. See Table 21.3-1 Interrupt Priority Level Setting for correct interrupt priority configuration.		

EIP1 – Extensive Interrupt Priority 1

7	6	5	4	3	2	1	0
-	-	-	-	-	PWKT	PT3	PS_1
-	-	-	-	-	R/W	R/W	R/W

Address: FEH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
2	PWKT	WKT interrupt priority low bit
1	PT3	Timer 3 interrupt priority low bit
0	PS_1	Serial port 1 interrupt priority low bit
Note : EIP1 is used in combination with the EIPH1 to determine the priority of each interrupt source. See Table 21.3-1 Interrupt Priority Level Setting for correct interrupt priority configuration.		

EIPH1 – Extensive Interrupt Priority High 1

7	6	5	4	3	2	1	0
-	-	-	-	-	PWKTH	PT3H	PSH_1
-	-	-	-	-	R/W	R/W	R/W

Address: FFH, Page: 0 Reset value: 0000 0000b

Bit	Name	Description
2	PWKTH	WKT interrupt priority high bit
1	PT3H	Timer 3 interrupt priority high bit
0	PSH_1	Serial port 1 interrupt priority high bit
Note : EIPH1 is used in combination with the EIP1 to determine the priority of each interrupt source. See Table 21.3-1 Interrupt Priority Level Setting for correct interrupt priority configuration.		

21.4 Interrupt Service

The interrupt flags are sampled every system clock cycle. In the same cycle, the sampled interrupts are polled and their priority is resolved. If certain conditions are met then the hardware will execute an internally generated LCALL instruction, which will vector the process to the appropriate interrupt vector address. The conditions for generating the LCALL are,

1. An interrupt of equal or higher priority is not currently being serviced.
2. The current polling cycle is the last cycle of the instruction currently being executed.

3. The current instruction does not involve a write to any enabling or priority setting bits and is not a RETI.

If any of these conditions are not met, then the LCALL will not be generated. The polling cycle is repeated every system clock cycle. If an interrupt flag is active in one cycle but not responded to for the above conditions are not met, if the flag is not still active when the blocking condition is removed, the denied interrupt will not be serviced. This means that the interrupt flag, which was once active but not serviced is not remembered. Every polling cycle is new.

The processor responds to a valid interrupt by executing an LCALL instruction to the appropriate service routine. This action may or may not clear the flag, which caused the interrupt according to different interrupt source. The hardware LCALL behaves exactly like the software LCALL instruction. This instruction saves the Program Counter contents onto the Stack RAM but does not save the Program Status Word (PSW). The PC is reloaded with the vector address of that interrupt, which caused the LCALL. Execution continues from the vectored address until an RETI instruction is executed. On execution of the RETI instruction, the processor pops the Stack and loads the PC with the contents at the top of the stack. User should take care that the status of the stack. The processor does not notice anything if the stack contents are modified and will proceed with execution from the address put back into PC. Note that a simple RET instruction would perform exactly the same process as a RETI instruction, but it would not inform the Interrupt controller that the interrupt service routine is completed. RET would leave the controller still thinking that the service routine is underway, making future interrupts impossible.

21.5 Interrupt Latency

The response time for each interrupt source depends on several factors, such as the nature of the interrupt and the instruction underway. Each interrupt flags are polled and priority decoded each system clock cycle. If a request is active and all three previous conditions are met, then the hardware generated LCALL is executed. This LCALL itself takes 4 clock cycles to be completed. Thus, there is a minimum reaction time of 5 clock cycles between the interrupt flag being set and the interrupt service routine being executed.

A longer response time should be anticipated if any of the three conditions are not met. If a higher or equal priority is being serviced, then the interrupt latency time obviously depends on the nature of the service routine currently being executed. If the polling cycle is not the last clock cycle of the instruction being executed, then an additional delay is introduced. The maximum response time (if no other interrupt is currently being serviced or the new interrupt is of greater priority) occurs if the device is performing a RETI, and then executes a longest 6-clock-cycle instruction as the next instruction. From the time an interrupt source is activated (not detected), the longest reaction time is 16 clock cycles. This period includes 5 clock cycles to complete RETI, 6 clock cycles to complete the longest

instruction, 1 clock cycle to detect the interrupt, and 4 clock cycles to complete the hardware LCALL to the interrupt vector location.

Thus in a single-interrupt system the interrupt response time will always be more than 5 clock cycles and not more than 16 clock cycles.

21.6 External Interrupt Pins

The external interrupt $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ can be used as interrupt sources. They are selectable to be either edge or level triggered depending on bits IT0 (TCON.0) and IT1 (TCON.2). The bits IE0 (TCON.1) and IE1 (TCON.3) are the flags those are checked to generate the interrupt. In the edge triggered mode, the $\overline{\text{INT0}}$ or $\overline{\text{INT1}}$ inputs are sampled every system clock cycle. If the sample is high in one cycle and low in the next, then a high to low transition is detected and the interrupts request flag IE0 or IE1 will be set. Since the external interrupts are sampled every system clock, they have to be held high or low for at least one system clock cycle. The IE0 and IE1 are automatically cleared when the interrupt service routine is called. If the level triggered mode is selected, then the requesting source has to hold the pin low till the interrupt is serviced. The IE0 and IE1 will not be cleared by the hardware on entering the service routine. In the level triggered mode, IE0 and IE1 follows the inverse value of $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ pins. If interrupt pins continue to be held low even after the service routine is completed, the processor will acknowledge another interrupt request from the same source. Both $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ can wake up the device from the Power-down mode.

TCON – Timer 0 and 1 Control (Bit-addressable)

7	6	5	4	3	2	1	0
TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
R/W	R/W	R/W	R/W	R (level) R/W (edge)	R/W	R (level) R/W (edge)	R/W

Address: 88H, All pages Reset value: 0000 0000b

Bit	Name	Description
3	IE1	External interrupt 1 edge flag If IT1 = 1 (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine. If IT1 = 0 (low level trigger), this flag follows the inverse of the $\overline{\text{INT1}}$ input signal's logic level. Software cannot control it.
2	IT1	External interrupt 1 type select This bit selects by which type that $\overline{\text{INT1}}$ is triggered. 0 = $\overline{\text{INT1}}$ is low level triggered. 1 = $\overline{\text{INT1}}$ is falling edge triggered.

Bit	Name	Description
1	IE0	<p>External interrupt 0 edge flag</p> <p>If IT0 = 1 (falling edge trigger), this flag will be set by hardware when a falling edge is detected. It remain set until cleared via software or cleared by hardware in the beginning of its interrupt service routine.</p> <p>If IT0 = 0 (low level trigger), this flag follows the inverse of the $\overline{\text{INT0}}$ input signal's logic level. Software cannot control it.</p>
0	IT0	<p>External interrupt 0 type select</p> <p>This bit selects by which type that $\overline{\text{INT0}}$ is triggered.</p> <p>0 = $\overline{\text{INT0}}$ is low level triggered.</p> <p>1 = $\overline{\text{INT0}}$ is falling edge triggered.</p>

22 IN-APPLICATION-PROGRAMMING (IAP)

Unlike RAM's real-time operation, to update flash data often takes long time. Furthermore, it is a quite complex timing procedure to erase, program, or read flash data. The MS51 carried out the flash operation with convenient mechanism to help user re-programming the flash content by In-Application-Programming (IAP). IAP is an in-circuit electrical erasure and programming method through software.

After IAP enabling by setting IAPEN (CHPCON.0 with TA protected) and setting the enable bit in IAPUEN that allows the target block to be updated, user can easily fill the 16-bit target address in IAPAH and IAPAL, data in IAPFD, and command in IAPCN. Then the IAP is ready to begin by setting a triggering bit IAPGO (IAPTRG.0). Note that IAPTRG is also TA protected. At this moment, the CPU holds the Program Counter and the built-in IAP automation takes over to control the internal charge-pump for high voltage and the detail signal timing. The erase and program time is internally controlled disregard of the operating voltage and frequency. Nominally, a page-erase time is 5 ms and a byte-program time is 23.5 μ s. After IAP action completed, the Program Counter continues to run the following instructions. The IAPGO bit will be automatically cleared. An IAP failure flag, IAPFF (CHPCON.6), can be check whether the previous IAP operation was successful or not. Through this progress, user can easily erase, program, and verify the Flash Memory by just taking care of pure software.

22.1 IAP Commands

The MS51 provides a wide range of applications to perform IAP to APROM, LDROM, or CONFIG bytes. The IAP action mode and the destination of the flash block are defined by IAP control register IAPCN.

IAP Mode	IAPCN				IAPA[15:0] {IAPAH, IAPAL}	IAPFD[7:0]
	IAPB [1:0]	FOEN	FCEN	FCTRL [3:0]		
Company ID read	XX ^[1]	0	0	1011	X	DAH
Device ID read	XX	0	0	1100	Low-byte DID: 0000H High-byte DID: 0001H	Low-byte DID High-byte DID
96-bit Unique Code read	XX	0	0	0100	0000H to 000BH	Data out
APROM page-erase	00	1	0	0010	Address in ^[2]	FFH
LDROM page-erase	01	1	0	0010	Address in ^[2]	FFH
APROM byte-program	00	1	0	0001	Address in	Data in
LDROM byte-program	01	1	0	0001	Address in	Data in
APROM byte-read	00	0	0	0000	Address in	Data out
LDROM byte-read	01	0	0	0000	Address in	Data out
All CONFIG bytes erase	11	1	0	0010	0000H	FFH
CONFIG byte-program	11	1	0	0001	CONFIG0: 0000H CONFIG1: 0001H CONFIG2: 0002H CONFIG4: 0004H CONFIG6: 0005H	Data in
CONFIG byte-read	11	0	0	0000	CONFIG0: 0000H CONFIG1: 0001H CONFIG2: 0002H CONFIG4: 0004H CONFIG6: 0005H	Data out
Note: 1. "X" means "don't care". 2. Each page is 128 bytes size. Therefore, the address should be the address pointed to the target page						

Table 22.1-1 IAP Modes and Command Codes

22.2 Control register of IAP

The following registers are related to IAP processing.

CONFIG2

7	6	5	4	3	2	1	0
CBODEN	CBOV[2:0]			BOIAP	CBORST	-	-
R/W	R/W			R/W	R/W	-	-

Factory default value: 1111 1111b

Bit	Name	Description
3	BOIAP	<p>Brown-out inhibiting IAP</p> <p>This bit decide whether IAP erasing or programming is inhibited by brown-out status. This bit is valid only when brown-out detection is enabled.</p> <p>1 = IAP erasing or programming is inhibited if V_{DD} is lower than V_{BOD}.</p> <p>0 = IAP erasing or programming is allowed under any workable V_{DD}.</p>

CHPCON – Chip Control (TA protected)

Address: AFH, Page 0 Reset value: 0011 0000b

Bit	Name	Description
7:6	IAPB[1:0]	IAP control This byte is used for IAP command. For details, see Table 22.1-1 IAP Modes and Command Codes.
5	FOEN	
4	FCEN	
3:0	FCTRL[3:0]	

IAPAH – IAP Address High Byte

7	6	5	4	3	2	1	0
IAPA[15:8]							
R/W							

Address: A7H, Page 0 Reset value: 0000 0000b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
7:0	IAPA[15:8]	IAP address high byte IAPAH contains address IAPA[15:8] for IAP operations.

IAPAL – IAP Address Low Byte

7	6	5	4	3	2	1	0
IAPA[7:0]							
R/W							

Address: A6H, Page 0 Reset value: 0000 0000b

Bit	Name	Description
7:0	IAPA[7:0]	IAP address low byte IAPAL contains address IAPA[7:0] for IAP operations.

IAPFD – IAP Flash Data

7	6	5	4	3	2	1	0
IAPFD[7:0]							
R/W							

Address: AEH, Page 0 Reset value: 0000 0000b

Bit	Name	Description
7:0	IAPFD[7:0]	IAP flash data This byte contains flash data, which is read from or is going to be written to the Flash Memory. User should write data into IAPFD for program mode before triggering IAP processing and read data from IAPFD for read/verify mode after IAP processing is finished.

IAPTRG – IAP Trigger (TA protected)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	IAPGO
-	-	-	-	-	-	-	W

Address: A4H, Page 0 Reset value: 0000 0000b

Bit	Name	Description
7:1	-	Reserved

Bit	Name	Description
0	IAPGO	<p>IAP go</p> <p>IAP begins by setting this bit as logic 1. After this instruction, the CPU holds the Program Counter (PC) and the IAP hardware automation takes over to control the progress. After IAP action completed, the Program Counter continues to run the following instruction. The IAPGO bit will be automatically cleared and always read as logic 0.</p> <p>Before triggering an IAP action, interrupts (if enabled) should be temporarily disabled for hardware limitation.</p> <p>The program process should follows below.</p> <pre> CLR EA MOV TA,#0AAH MOV TA,#55H ORL IAPTRG,#01H (SETB EA) </pre>

22.3 IAP User Guide

IAP facilitates the updating flash contents in a convenient way; however, user should follow some restricted laws in order that the IAP operates correctly. Without noticing warnings will possible cause undetermined results even serious damages of devices. Furthermore, this paragraph will also support useful suggestions during IAP procedures.

(1) If no more IAP operation is needed, user should clear IAPEN (CHPCON.0). It will make the system void to trigger IAP unaware. Furthermore, IAP requires the HIRC running. If the external clock source is selected, disabling IAP will stop the HIRC for saving power consumption. Note that a write to IAPEN is TA protected.

(2) When the LOCK bit (CONFIG0.1) is activated, IAP reading, writing, or erasing can still be valid.

During IAP progress, interrupts (if enabled) should be disabled temporally by clearing EA bit for implement limitation.

Do not attempt to erase or program to a page that the code is currently executing. This will cause unpredictable program behavior and may corrupt program data.

22.4 Using Flash Memory as Data Storage

In general application, there is a need of data storage, which is non-volatile so that it remains its content even after the power is off. Therefore, in general application user can read back or update the data, which rules as parameters or constants for system control. The Flash Memory array of the MS51 supports IAP function and any byte in the Flash Memory array may be read using the MOVC instruction and thus is suitable for use as non-volatile data storage. IAP provides erase and program function that makes it easy for one or more bytes within a page to be erased and programmed in a

routine. IAP performs in the application under the control of the microcontroller's firmware. Be aware of Flash Memory writing endurance of 100,000 cycles. A demo is illustrated as follows.

22.5 In-System-Programming (ISP)

The Flash Memory supports both hardware programming and In-Application-Programming (IAP). If the product is just under development or the end product needs firmware updating in the hand of an end user, the hardware programming mode will make repeated programming difficult and inconvenient. In-System-Programming (ISP) makes it easy and possible. ISP performs Flash Memory updating without removing the microcontroller from the system. It allows a device to be re-programmed under software control. Furthermore, the capability to update the application firmware makes wide range of applications possible.

User can develop a custom Boot Code that resides in LDROM. The maximum size of LDROM is 4K Byte. User developed Boot Code can be re-programmed by parallel writer or In-Circuit-Programming (ICP) tool.

General speaking, an ISP is carried out by a communication between PC and MCU. PC transfers the new User Code to MCU through serial port. Then Boot Code receives it and re-programs into User Code through IAP commands. Nuvoton provides ISP firmware and PC application for MS51. It makes user quite easy perform ISP through UART port. Please visit Nuvoton 8-bit Microcontroller website: [Nuvoton 80C51 Microcontroller Technical Support](#). A simple ISP demo code is given below.

Assembly demo code:

```

23 POWER MANAGEMENT

The MS51 has several features that help user to control the power consumption of the device. The power reduced feature has two option modes: Idle mode and Power-down mode, to save the power consumption. For a stable current consumption, the state and mode of each pin should be taken care of. The minimum power consumption can be attained by giving the pin state just the same as the external pulls for example output 1 if pull-high is used or output 0 if pull-low. If the I/O pin is floating, user is recommended to leave it as quasi-bidirectional mode. If P2.0 is configured as a input-only pin, it should have an external pull-up or pull-low, or enable its internal pull-up by setting P20UP (P2S.7).

Address: 9FH, All pages

Reset value: see Table 7.1-1 Special Function Register Memory Map

Bit	Name	Description
1	PD	<p>Power-down mode</p> <p>Setting this bit puts CPU into Power-down mode. Under this mode, both CPU and peripheral clocks stop and Program Counter (PC) suspends. It provides the lowest power consumption. After CPU is woken up from Power-down, this bit will be automatically cleared via hardware and the program continue executing the interrupt service routine (ISR) of the very interrupt source that woke the system up before. After return from the ISR, the device continues execution at the instruction, which follows the instruction that put the system into Power-down mode.</p> <p>Note that If IDL bit and PD bit are set simultaneously, CPU will enter Power-down mode. Then it does not go to Idle mode after exiting Power-down.</p>
0	IDL	<p>Idle mode</p> <p>Setting this bit puts CPU into Idle mode. Under this mode, the CPU clock stops and Program Counter (PC) suspends but all peripherals keep activated. After CPU is woken up from Idle, this bit will be automatically cleared via hardware and the program continue executing the ISR of the very interrupt source that woke the system up before. After return from the ISR, the device continues execution at the instruction which follows the instruction that put the system into Idle mode.</p>

23.1 Idle Mode

Idle mode suspends CPU processing by holding the Program Counter. No program code are fetched and run in Idle mode. It forces the CPU state to be frozen. The Program Counter (PC), Stack Pointer (SP), Program Status Word (PSW), Accumulator (ACC), and the other registers hold their contents during Idle mode. The port pins hold the logical states they had at the time Idle was activated. Generally, it saves considerable power of typical half of the full operating power.

Since the clock provided for peripheral function logic circuit like timer or serial port still remain in Idle mode, the CPU can be released from the Idle mode with any of enabled interrupt sources. User can put the device into Idle mode by writing 1 to the bit IDL (PCON.0). The instruction that sets the IDL bit is the last instruction that will be executed before the device enters Idle mode.

The Idle mode can be terminated in two ways. First, as mentioned, any enabled interrupt will cause an exit. It will automatically clear the IDL bit, terminate Idle mode, and the interrupt service routine (ISR) will be executed. After using the RETI instruction to jump out of the ISR, execution of the program will be the one following the instruction, which put the CPU into Idle mode. The second way to terminate Idle mode is with any reset other than software reset. Remember that if Watchdog reset is used to exit Idle mode, the WIDPD (WDCON.4) needs to be set 1 to let WDT keep running in Idle mode.

23.2 Power-Down Mode

Power-down mode is the lowest power state that the MS51 can enter. It remain the power consumption as A "Ma" level by stopping the system clock source. Both of CPU and peripheral functions like Timers or UART are frozen. Flash memory is put into its stop mode. All activity is completely stopped and the power consumption is reduced to the lowest possible value. The device can be put into Power-down mode by writing 1 to bit PD (PCON.1). The instruction that does this action will be the last instruction to be executed before the device enters Power-down mode. In the Power-down mode, RAM maintains its content. The port pins output the values held by their own state before Power-down respectively.

There are several ways to exit the MS51 from the Power-down mode. The first is with all resets except software reset. Brown-out reset will also wake up CPU from Power-down mode. Be sure that brown-out detection is enabled before the system enters Power-down. However, for least power consumption, it is recommended to enable low power BOD in Power-down mode. Of course the external pin reset and power-on reset will remove the Power-down status. After the external reset or power-on reset. The CPU is initialized and start executing program code from the beginning.

The second way to wake the MS51 up from the Power-down mode is by an enabled external interrupt. The trigger on the external pin will asynchronously restart the system clock. After oscillator is stable, the device executes the interrupt service routine (ISR) for the corresponding external interrupt. After the ISR is completed, the program execution returns to the instruction after the one, which puts the device into Power-down mode and continues. Interrupts that allows to wake up CPU from Power-down mode includes external interrupt $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$, pin interrupt, WDT interrupt, WKT interrupt, and brown-out interrupt.

24 CLOCK SYSTEM

The MS51 has a wide variety of clock sources and selection features that allow it to be used in a wide range of applications while maximizing performance and minimizing power consumption. The MS51 provides three options of the system clock sources including internal oscillator, or external clock from XIN pin via software. The MS51 is embedded with two internal oscillators: one 10 kHz low-speed and one 16 MHz high-speed, which is factory trimmed to $\pm 2\%$ under all conditions. A clock divider CKDIV is also available on MS51 for adjustment of the flexibility between power consumption and operating performance.

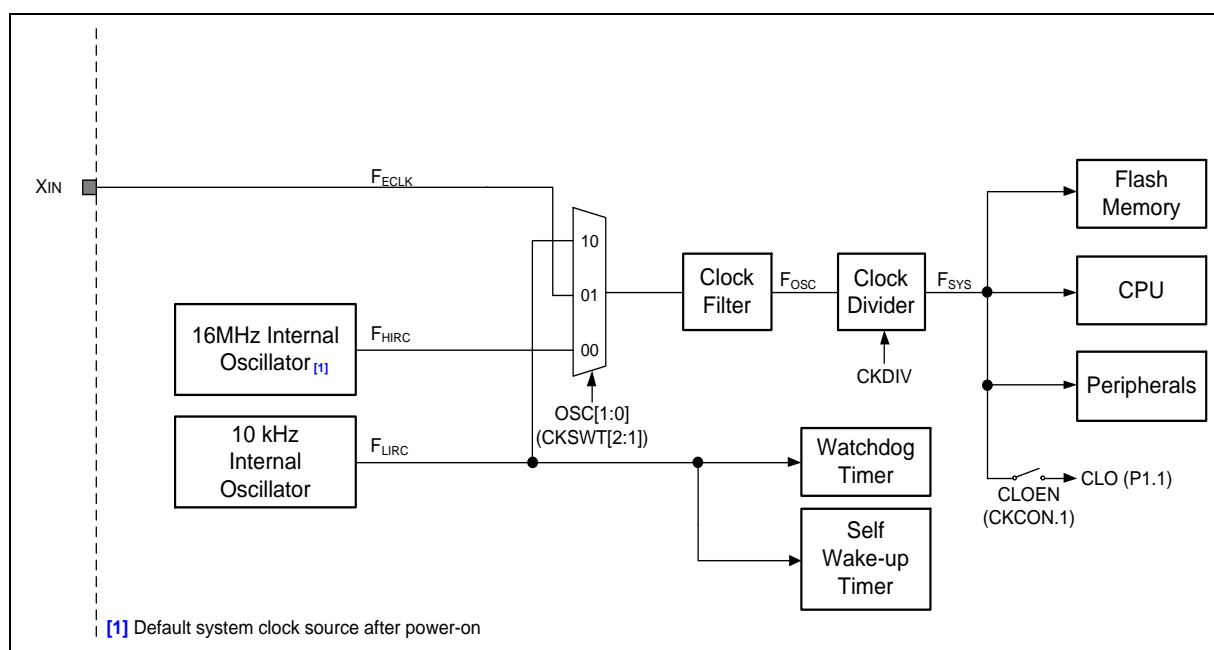

Figure 23.2-1 Clock System Block Diagram

24.1 System Clock Sources

There are a total of three system clock sources selectable in the MS51 including high-speed internal oscillator, low-speed internal oscillator and external clock input. Each of them can be the system clock source in the MS51. Different active system clock sources also affect multi-function of P3.0/XIN.

24.1.1 Internal Oscillators

There are two internal oscillators in the MS51 – one high-speed internal oscillator (HIRC) 16 MHz or 24MHz selectable base on HIRC24 (RCTRIM1.4) define. And one 10 kHz low-speed (LIRC). Both of them can be selected as the system clock. HIRC can be enabled by setting HIRCEN (CKEN.5). LIRC is enabled after device is powered up. User can set OSC[1:0] (CKSWT [2:1]) as [1,1] to select the HIRC as the system clock. By setting OSC[1:0] as [1,0], LIRC will be selected as the system clock. Note that after the MS51 is powered, HIRC and LIRC will be both enabled and HIRC is default selected as the system clock source. While using internal oscillators, XIN automatically switch as one

general purpose I/O P3.0 to expand the number of general purpose I/O. The I/O output mode of P3.0 can be selected by configuring P3M1 and P3M2 registers.

Since HIRC value defined by a 9-bit data, user can adjust SFR to modify HIRC value, each bit of this value is about modify 40KHz. Decrease this value will cause HIRC more quick and add one means HIRC speed slower about 40KHz.

Following shows two Byte combine the 9-bit internal RC trim value. And HIRC 24MHz define bit.

RCTRIM0 –High Speed Internal Oscillator 16 MHz Trim 0 (TA protected)

7	6	5	4	3	2	1	0
HIRCTRIM[8:1]							
R/W							

Address: 84H Reset value: 16 MHz HIRC value

RCTRIM1 –High Speed Internal Oscillator 16 MHz Trim 1 (TA protected)

7	6	5	4	3	2	1	0
-	-	-	HIRC24	-	-	-	HIRCTRIM.0
-	-	-	R/W	-	-	-	R/W

Address: 85H Reset value: 16 MHz HIRC value

Note: since default RCTRIM0 and RCTRIM1 value is base on 16MHz, if base on this value then modify HIRC24(RCTIM1.4) to enable 24MHz HIRC mode, the real HIRC deviation will more than 1%. Suggest reload the 24MHz HIRC value from after UID, and check value bit 4 to confirm this value is suit for 24MHz application.

24.2 System Clock Switching

The MS51 supports clock source switching on-the-fly by controlling CKSWT and CKEN registers via software. It provides a wide flexibility in application. Note that these SFRs are writing TA protected for precaution. With this clock source control, the clock source can be switched between the external clock source and the internal oscillator, even between the high and low-speed internal oscillator. However, during clock source switching, the device requires some amount of warm-up period for an original disabled clock source. Therefore, use should follow steps below to ensure a complete clock source switching. User can enable the target clock source by writing proper value into CKEN register, wait for the clock source stable by polling its status bit in CKSWT register, and switch to the target clock source by changing OSC[1:0] (CKSWT[2:1]). After these step, the clock source switching is successful and then user can also disable the original clock source if power consumption is concerned. Note that if not following the steps above, the hardware will take certain actions to deal with such illegal operations as follows.

1. If user tries to disable the current clock source by changing CKEN value, the device will ignore this action. The system clock will remain the original one and CKEN will remain the original value.

2. If user tries to switch the system clock source to a disabled one by changing OSC[1:0] value, OSC[1:0] value will be updated right away. But the system clock will remain the original one and CKSWTF flag will be set by hardware.

3. Once user switches the system clock source to an enabled but still instable one, the hardware will wait for stabilization of the target clock source and then switch to it in the background. During this waiting period, the device will continue executing the program with the original clock source and CKSWTF will be set as 1. After the stable flag of the target clock source (see CKSWT[7:3]) is set and the clock source switches successfully, CKSWTF will be cleared as 0 automatically by hardware.

CKSWT – Clock Switch (TA protected)

7	6	5	4	3	2	1	0
-	-	HIRCST	-	ECLKST	OSC[1:0]		-

Bit	Name	Description
7:6	EXTEN[1:0]	External clock source enable 11 = External clock input via XIN Enabled. Others = external clock input is disable. P30 work as general purpose I/O.
5	HIRCEN	High-speed internal oscillator 16 MHz enable 0 = The high-speed internal oscillator Disabled. 1 = The high-speed internal oscillator Enabled. Note that once IAP is enabled by setting IAPEN (CHPCON.0), the high-speed internal 16 MHz oscillator will be enabled automatically. The hardware will also set HIRCEN and HIRCST bits. After IAPEN is cleared, HIRCEN and EHRCST resume the original values.
4:1	-	Reserved
0	CKSWTF	Clock switch fault flag 0 = The previous system clock source switch was successful. 1 = User tried to switch to an instable or disabled clock source at the previous system clock source switch. If switching to an instable clock source, this bit remains 1 until the clock source is stable and switching is successful.

24.3 System Clock Divider

The oscillator frequency (F_{OSC}) can be divided down, by an integer, up to 1/510 by configuring a dividing register, CKDIV, to provide the system clock (F_{SYS}). This feature makes it possible to temporarily run the MCU at a lower rate, reducing power consumption. By dividing the clock, the MCU can retain the ability to respond to events other than those that can cause interrupts (i.e. events that allow exiting the Idle mode) by executing its normal program at a lower rate. This can often result in lower power consumption than in Idle mode. This can allow bypassing the oscillator start-up time in cases where Power-down mode would otherwise be used. The value of CKDIV may be changed by the program at any time without interrupting code execution.

CKDIV – Clock Divider

7	6	5	4	3	2	1	0
CKDIV[7:0]							
R/W							

Address: C1H, Page 1 Reset value: 0000 0000b

Bit	Name	Description
7:0	CKDIV[7:0]	Clock divider The system clock frequency F_{SYS} follows the equation below according to CKDIV value. $F_{SYS} = F_{OSC}$, while CKDIV = 00H, and $F_{SYS} = \frac{F_{OSC}}{2 \times CKDIV}$, while CKDIV = 01H to FFH.

24.4 System Clock Output

The MS51 provides a CLO pin (P1.1) that outputs the system clock. Its frequency is the same as F_{SYS} . The output enable bit is CLOEN (CKCON.1). CLO output stops when device is put in its Power-down mode because the system clock is turned off. Note that when noise problem or power consumption is important issue, user had better not enable CLO output.

CKCON – Clock Control

7	6	5	4	3	2	1	0
-	PWMCKS	-	T1M	T0M	-	CLOEN	
-	R/W	-	R/W	R/W	-	R/W	-

Address: 8EH, Page: 0

Bit	Name	Description
1	CLOEN	System clock output enable 0 = System clock output Disabled. 1 = System clock output Enabled from CLO pin (P1.1).

25 POWER MONITORING

To prevent incorrect execution during power up and power drop, The MS51 provide three power monitor functions, power-on detection and brown-out detection.

25.1 Power-On Detection

The power-on detection function is designed for detecting power up after power voltage reaches to a level where system can work. After power-on detected, the POF (PCON.4) will be set 1 to indicate a cold reset, a power-on reset complete. The POF flag can be cleared via software.

PCON – Power Control

7	6	5	4	3	2	1	0
SMOD	SMOD0	LPR	POF	GF1	GF0	PD	IDL
R/W	R/W	RW	R/W	R/W	R/W	R/W	R/W

Address: 87H, All pagesReset value: see Table 7.1-1 Special Function Register Memory Map

Bit	Name	Description
4	POF	Power-on reset flag This bit will be set as 1 after a power-on reset. It indicates a cold reset, a power-on reset complete. This bit remains its value after any other resets. This flag is recommended to be cleared via software.

25.2 Brown-Out Detection (BOD)

The other power monitoring function brown-out detection (BOD) circuit is used for monitoring the V_{DD} level during execution. There are eight CONFIG selectable brown-out trigger levels available for wide voltage applications. These eight nominal levels are 1.8V, 2.0V, 2.4V, 2.7V, 3.0V, 3.7V and 4.4V selected via setting CBOV[2:0] (CONFIG2[6:4]). BOD level can also be changed by setting BOV[2:0] (BODCON0[6:4]) after power-on. When V_{DD} drops to the selected brown-out trigger level (V_{BOD}), the BOD logic will either reset the MCU or request a brown-out interrupt. User may decide to being reset or generating a brown-out interrupt according to different applications. V_{BOD} also can be set by software after power-on. Note that BOD output is not available until 2~3 LIRC clocks after software enabling.

The BOD will request the interrupt while V_{DD} drops below V_{BOD} while BORST (BODCON0.2) is 0. In this case, BOF (BODCON0.3) will be set as 1. After user cleared this flag whereas V_{DD} remains below V_{BOD} , BOF will not set again. BOF just acknowledge user a power drop occurs. The BOF will also be set as 1 after V_{DD} goes higher than V_{BOD} to indicate a power resuming. The BOD circuit provides an useful status indicator BOS (BODCON0.0), which is helpful to tell a brown-out event or power resuming event occurrence. If the BORST bit is set as 1, this will enable brown-out reset function. After a brown-out reset, BORF (BODCON0.1) will be set as 1 via hardware. It will not be altered by

reset other than power-on. This bit can be cleared by software. Note that all bits in BODCON0 is writing protected by timed access (TA).

The MS51 provides low power BOD mode for saving current consumption and remaining BOD functionality with limited detection response. By setting LPBOD[1:0] (BODCON1[2:1]), the BOD circuit can be periodically enabled to sense the power voltage nominally every 1.6 ms, 6.4 ms, or 25.6 ms. It saves much power but also provides low-speed power voltage sensing. Note that the hysteresis feature will disappear in low power BOD mode.

For a noise sensitive system, the MS51 has a BOD filter which filters the power noise to avoid BOD event triggering unconsciously. The BOD filter is enabled by default and can be disabled by setting BODFLT (BODCON1.0) as 0 if user requires a rapid BOD response. The minimum brown-out detect pulse width is listed in LPBOD[1:0] (BODCON1)

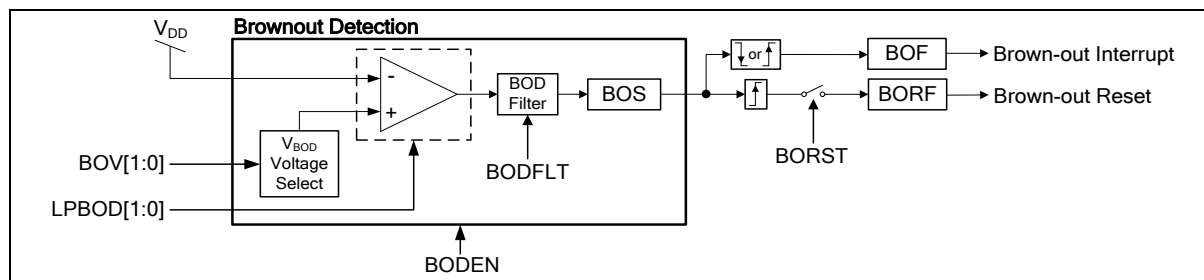

Figure 25.2-1 Brown-out Detection Block Diagram

CONFIG2

7	6	5	4	3	2	1	0

Table 25.2-2 Minimum Brown-out Detect Pulse Width

26 RESET

The MS51 has several options to place device in reset condition. It also offers the software flags to indicate the source, which causes a reset. In general, most SFR go to their Reset value irrespective of the reset condition, but there are several reset source indicating flags whose state depends on the source of reset. User can read back these flags to determine the cause of reset using software. There are five ways of putting the device into reset state. They are power-on reset, brown-out reset, external reset, WDT reset, and software reset.

26.1 Power-On Reset and Low Voltage Reset

The MS51 incorporates an internal power-on reset (POR) and a low voltage reset (LVR). During a power-on process of rising power supply voltage V_{DD} , the POR or LVR will hold the MCU in reset mode when V_{DD} is lower than the voltage reference thresholds. This design makes CPU not access program flash while the V_{DD} is not adequate performing the flash reading. If an undetermined operating code is read from the program flash and executed, this will put CPU and even the whole system in to an erroneous state. After a while, V_{DD} rises above the threshold where the system can work, the selected oscillator will start and then program code will execute from 0000H. At the same time, a power-on flag POF (PCON.4) will be set 1 to indicate a cold reset, a power-on process complete. Note that the contents of internal RAM will be undetermined after a power-on. It is recommended that user gives initial values for the RAM block.

The POF is recommended to be cleared to 0 via software to check if a cold reset or warm reset performed after the next reset occurs. If a cold reset caused by power off and on, POF will be set 1 again. If the reset is a warm reset caused by other reset sources, POF will remain 0. User may take a different course to check other reset flags and deal with the warm reset event. For detailed electrical characteristics, refer to the table 35-7 and 35-8.

PCON – Power Control

7	6	5	4	3	2	1	0
SMOD	SMOD0	LPR	POF	GF1	GF0	PD	IDL
R/W	R/W	RW	R/W	R/W	R/W	R/W	R/W

Address: 87H

Reset value: POR, 0001 0000b Others, 000U 0000b

Bit	Name	Description
4	POF	Power-on reset flag This bit will be set as 1 after a power-on reset. It indicates a cold reset, a power-on reset complete. This bit remains its value after any other resets. This flag is recommended to be cleared via software.

26.2 Brown-Out Reset

The brown-out detection circuit is used for monitoring the V_{DD} level during execution. When V_{DD} drops to the selected brown-out trigger level (V_{BOD}), the brown-out detection logic will reset the MCU if BORST (BODCON0.2) setting 1. After a brown-out reset, BORF (BODCON0.1) will be set as 1 via hardware. BORF will not be altered by any reset other than a power-on reset or brown-out reset itself. This bit can be set or cleared by software.

BODCON0 – Brown-out Detection Control 0 (TA protected)

7	6	5	4	3	2	1	0
BODEN	BOV[2:0]			BOF	BORST	BORF	BOS
R/W	R/W			R/W	R/W	R/W	R

Address: A3H Reset value: POR,CCCC XC0Xb / BOD, UUUU XU1Xb / Others,UUUU XUUXb

Bit	Name	Description
1	BORF	Brown-out reset flag When the MCU is reset by brown-out event, this bit will be set via hardware. This flag is recommended to be cleared via software.

26.3 External Reset and Hard Fault Reset

The external reset pin \overline{RST} is an input with a Schmitt trigger. An external reset is accomplished by holding the \overline{RST} pin low for at least 24 system clock cycles to ensure detection of a valid hardware reset signal. The reset circuitry then synchronously applies the internal reset signal. Thus, the reset is a synchronous operation and requires the clock to be running to cause an external reset.

Once the device is in reset condition, it will remain as long as \overline{RST} pin is low. After the \overline{RST} high is removed, the MCU will exit the reset state and begin code executing from address 0000H. If an external reset applies while CPU is in Power-down mode, the way to trigger a hardware reset is slightly different. Since the Power-down mode stops system clock, the reset signal will asynchronously cause the system clock resuming. After the system clock is stable, MCU will enter the reset state.

There is a RSTPINF (AUXR0.6) flag, which indicates an external reset took place. After the external reset, this bit will be set as 1 via hardware. RSTPINF will not change after any reset other than a power-on reset or the external reset itself. This bit can be cleared via software.

Hard Fault reset will occur if CPU fetches instruction address over flash size, HardF (AUXR0.5) flag will be set via hardware. HardF will not change after any reset other than a power-on reset or the external reset itself. This bit can be cleared via software. If MCU run in OCD debug mode and OCDEN = 0, hard fault reset will be disabled. Only HardF flag be asserted.

AUXR0 – Auxiliary Register 0

7	6	5	4	3	2	1	0
SWRF	RSTPINF	HardF	HardFInt	GF2	-	0	DPS
R/W	R/W	R/W	R/W	R/W	-	R	R/W

Address: A2H, Page:0 Reset value: see Table 7.1-1 Special Function Register Memory Map

Bit	Name	Description
6	RSTPINF	External reset flag When the MCU is reset by the external reset, this bit will be set via hardware. It is recommended that the flag be cleared via software.
5	HardF	Hard Fault reset flag Once CPU fetches instruction address over flash size while EHFI (EIE1.4)=0, MCU will reset and this bit will be set via hardware. It is recommended that the flag be cleared via software. Note: If MCU run in OCD debug mode and OCDEN = 0, Hard fault reset will disable. Only HardF flag be asserted.

26.4 Watchdog Timer Reset

The WDT is a free running timer with programmable time-out intervals and a dedicated internal clock source. User can clear the WDT at any time, causing it to restart the counter. When the selected time-out occurs but no software response taking place for a while, the WDT will reset the system directly and CPU will begin execution from 0000H.

Once a reset due to WDT occurs, the WDT reset flag WDTRF (WDCON.3) will be set. This bit keeps unchanged after any reset other than a power-on reset or WDT reset itself. User can clear WDTRF via software.

WDCON – Watchdog Timer Control (TA protected)

7	6	5	4	3	2	1	0
WDTR	WDCLR	WDTF	WIDPD	WDTRF	WDPS[2:0]		
R/W	R/W	R/W	R/W	R/W	R/W		

Address: AAH, Page 0 Reset value: see Table 7.1-1 Special Function Register Memory Map

Bit	Name	Description
3	WDTRF	WDT reset flag When the CPU is reset by WDT time-out event, this bit will be set via hardware. This flag is recommended to be cleared via software after reset.

26.5 Software Reset

The MS51 provides a software reset, which allows the software to reset the whole system just similar to an external reset, initializing the MCU as it reset state. The software reset is quite useful in the end of an ISP progress. For example, if an ISP of Boot Code updating User Code finishes, a software reset can be asserted to re-boot CPU to execute new User Code immediately. Writing 1 to SWRST (CHPCON.7) will trigger a software reset. Note that this bit is writing TA protection. The instruction that sets the SWRST bit is the last instruction that will be executed before the device reset. See demo code below.

If a software reset occurs, SWRF (AUXR0.7) will be automatically set by hardware. User can check it as the reset source indicator. SWRF keeps unchanged after any reset other than a power-on reset or software reset itself. SWRF can be cleared via software.

CHPCON – Chip Control (TA protected)

7	6	5	4	3	2	1	0
SWRST	IAPFF	-	-	-	-	BS	IAPEN
W	R/W	-	-	-	-	R/W	R/W

Address: 9FH, all pages Reset value: Software 0000 00U0b, Others 0000 00C0b

Bit	Name	Description
7	SWRST	Software reset To set this bit as logic 1 will cause a software reset. It will automatically be cleared via hardware after reset is finished.

AUXR0 – Auxiliary Register 0

7	6	5	4	3	2	1	0
SWRF	RSTPINF	HardF	HardFInt	GF2	-	0	DPS
R/W	R/W	R/W	R/W	R/W	-	R	R/W

Address: A2H, Page:0 Reset value: see Table 7.1-1 Special Function Register Memory Map

Bit	Name	Description
7	SWRF	Software reset flag When the MCU is reset via software reset, this bit will be set via hardware. It is recommended that the flag be cleared via software.

The software demo code is listed below.

```
ANL  AUXR0, #01111111b    ;software reset flag clear
CLR  EA
MOV  TA, #0Aah
MOV  TA, #55h
ORL  CHPCON, #10000000b    ;software reset
```

26.6 Boot Select

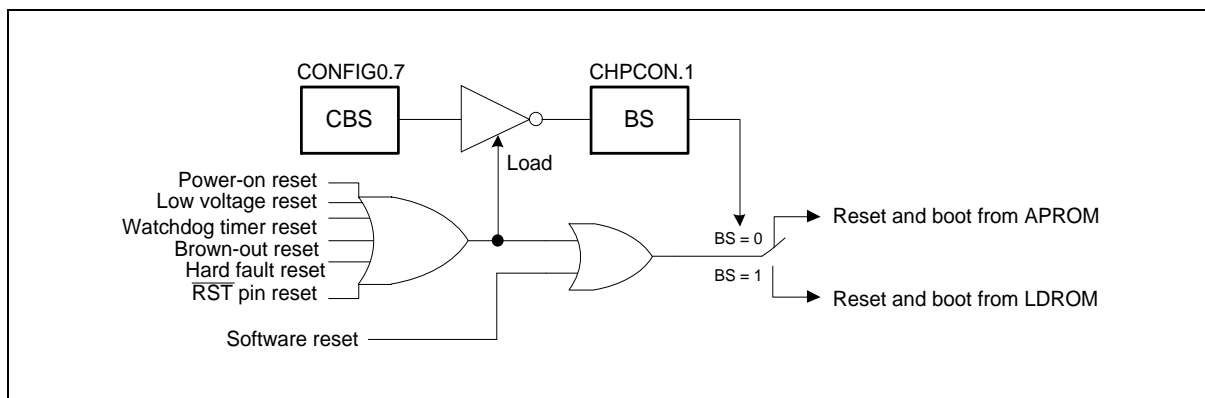

Figure 26.6-1 Boot Selecting Diagram

The MS51 provides user a flexible boot selection for variant application. The SFR bit BS in CHPCON.1 determines MCU booting from APROM or LDROM after any source of reset. If reset occurs and BS is 0, MCU will reboot from address 0000H of APROM. Else, the CPU will reboot from address 0000H of LDROM. Note that BS is loaded from the inverted value of CBS bit in CONFIG0.7 after all resets except software reset.

CONFIG0

7	6	5	4	3	2	1	0
CBS	-	OCDPWM	OCDEN	-	-	LOCK	-
R/W	-	R/W	R/W	-	-	R/W	-

Factory default value: 1111 1111b

Bit	Name	Description
7	CBS	CONFIG boot select This bit defines from which block that MCU re-boots after resets except software reset. 1 = MCU will re-boot from APROM after resets except software reset. 0 = MCU will re-boot from LDROM after resets except software reset.

CHPCON – Chip Control (TA protected)

7	6	5	4	3	2	1	0
SWRST	IAPFF	-	-	-	-	BS ^[1]	IAPEN
W	R/W	-	-	-	-	R/W	R/W

Address: 9FH, All pages Reset value: Software: 0000 00U0b / others: 0000 00C0b

Bit	Name	Description
-----	------	-------------

Bit	Name	Description
1	BS	Boot select This bit defines from which block that MCU re-boots after all resets. 0 = MCU will re-boot from APROM after all resets. 1 = MCU will re-boot from LDROM after all resets.

[1] BS is initialized by being loaded from the inverted value of CBS bit in CONFIG0.7 after resets except software reset. It keeps unchanged after software reset.

After the MCU is released from reset state, the hardware will always check the BS bit instead of the CBS bit to determine from which block that the device reboots.

26.7 Reset State

The reset state besides power-on reset does not affect the on-chip RAM. The data in the RAM will be preserved during the reset. After the power-on reset the RAM contents will be indeterminate.

After a reset, most of SFR go to their initial values except bits, which are affected by different reset events.. The Program Counter is forced to 0000H and held as long as the reset condition is applied. Note that the Stack Pointer is also reset to 07H and thus the stack contents may be effectively lost during the reset event even though the RAM contents are not altered.

After a reset, all peripherals and interrupts are disabled. The I/O port latches resumes FFH and I/O mode input-only.

27 AUXILIARY FEATURES

27.1 Dual DPTRs

The original 8051 contains one DPTR (data pointer) only. With single DPTR, it is difficult to move data from one address to another with wasting code size and low performance. The MS51 provides two data pointers. Thus, software can load both a source and a destination address when doing a block move. Once loading, the software simply switches between DPTR and DPTR1 by the active data pointer selection DPS (AUXR0.0) bit.

An example of 64 bytes block move with dual DPTRs is illustrated below. By giving source and destination addresses in data pointers and activating cyclic makes block RAM data move more simple and efficient than only one DPTR. The `INC AUXR0` instruction is the shortest (2 bytes) instruction to accomplish DPTR toggling rather than `ORL` or `ANL`. For AUXR0.1 contains a hard-wired 0, it allows toggling of the DPS bit by incrementing AUXR0 without interfering with other bits in the register.

```
MOV    R0, #64                ;number of bytes to move
MOV    DPTR, #D_Addr          ;load destination address
INC     AUXR0                  ;change active DPTR
MOV    DPTR, #S_Addr          ;load source address
LOOP:
MOVX   A, @DPTR               ;read source data byte
INC     AUXR0                  ;change DPTR to destination
MOVX   @DPTR, A               ;write data to destination
INC     DPTR                   ;next destination address
INC     AUXR0                  ;change DPTR to source
INC     DPTR                   ;next source address
DJNZ   R0, LOOP
INC     AUXR0                  ;(optional) restore DPS
```

AUXR0 also contains a general purpose flag GF2 in its bit 3 that can be set or cleared by the user via software.

DPL – Data Pointer Low Byte

7	6	5	4	3	2	1	0
DPL[7:0]							
R/W							

Address: 82H, All pages Reset value: 0000 0000b

Bit	Name	Description
7:0	DPL[7:0]	Data pointer low byte This is the low byte of 16-bit data pointer. DPL combined with DPH serve as a 16-bit data pointer DPTR to access indirect addressed RAM or Program Memory. DPS (AUXR0.0) bit decides which data pointer, DPTR or DPTR1, is activated.

DPH – Data Pointer High Byte

7	6	5	4	3	2	1	0
DPH[7:0]							
R/W							

Address: 83H, All pages Reset value: 0000 0000b

Bit	Name	Description
7:0	DPH[7:0]	Data pointer high byte This is the high byte of 16-bit data pointer. DPH combined with DPL serve as a 16-bit data pointer DPTR to access indirect addressed RAM or Program Memory. DPS (AUXR0.0) bit decides which data pointer, DPTR or DPTR1, is activated.

AUXR1 – Auxiliary Register 1

7	6	5	4	3	2	1	0
SWRF	RSTPINF	HardF	-	GF2	UART0PX	0	DPS
R/W	R/W	R/W	-	R/W	R/W	R	R/W

Address: A2H Reset value: POR 0000 0000b, Software 1U00 0000b, nRESET pin U100 0000b, Others UUU0 0000b

Bit	Name	Description
3	GF2	General purpose flag 2 The general purpose flag that can be set or cleared by the user via software.
0	DPS	Data pointer select 0 = Data pointer 0 (DPTR) is active by default. 1 = Data pointer 1 (DPTR1) is active. After DPS switches the activated data pointer, the previous inactivated data pointer remains its original value unchanged.

27.2 96-Bit Unique Code

Before shipping out, each MS51 chip was factory pre-programmed with a 96-bit width serial number, which is guaranteed to be unique. The serial number is called Unique Code. The user can read the Unique Code only by IAP command. Please see Chapter 22.1 IAP Commands.

28 ON-CHIP-DEBUGGER (OCD)

28.1 Functional Description

The MS51 is embedded in an on-chip-debugger (OCD) providing developers with a low cost method for debugging user code, which is available on each package. The OCD gives debug capability of complete program flow control with eight hardware address breakpoints, single step, free running, and non-intrusive commands for memory access. The OCD system does not occupy any locations in the memory map and does not share any on-chip peripherals.

When the OCDEN (CONFIG0.4) is programmed as 0 and LOCK (CONFIG0.1) remains un-programmed as 1, the OCD is activated. The OCD cannot operate if chip is locked. The OCD system uses a two-wire serial interface, OCDDA and OCDCK, to establish communication between the target device and the controlling debugger host. OCDDA is an input/output pin for debug data transfer and OCDCK is an input pin for synchronization with OCDDA data. The \overline{RST} pin is also necessary for OCD mode entry and exit. The MS51 supports OCD with Flash Memory control path by ICP writer mode, which shares the same three pins of OCD interface.

The MS51 uses OCDDA, OCDCK, and \overline{RST} pins to interface with the OCD system. When designing a system where OCD will be used, the following restrictions must be considered for correct operation:

1. \overline{RST} cannot be connected directly to V_{DD} and any external capacitors connected must be removed.
2. All external reset sources must be disconnected.
3. Any external component connected on OCDDA and OCDCK must be isolated.

28.2 Limitation of OCD

The MS51 is a fully-featured microcontroller that multiplexes several functions on its limited I/O pins. Some device functionality must be sacrificed to provide resources for OCD system. The OCD has the following limitations:

1. The \overline{RST} pin needs to be used for OCD mode selection.
2. The OCDDA pin is physically located on the same pin P5.0. Therefore, neither its I/O function nor shared multi-functions can be emulated.
3. The OCDCK pin is physically located on the same pin as P5.1. Therefore, neither its I/O function nor shared multi-functions can be emulated.

4. When the system is in Idle or Power-down mode, it is invalid to perform any accesses because parts of the device may not be clocked. A read access could return garbage or a write access might not succeed.

5. HIRC cannot be turned off because OCD uses this clock to monitor its internal status. The instruction that turns off HIRC affects nothing if executing under debug mode. When CPU enters its Power-down mode under debug mode, HIRC keeps turning on.

The MS51 OCD system has another limitation that non-intrusive commands cannot be executed at any time while the user's program is running. Non-intrusive commands allow a user to read or write MCU memory locations or access status and control registers with the debug controller. A reading or writing memory or control register space is allowed only when MCU is under halt condition after a matching of the hardware address breakpoint or a single step running.

CONFIG0

7	6	5	4	3	2	1	0
CBS	-	OCDPWM	OCDEN	-	-	LOCK	-
R/W	-	R/W	R/W	-	-	R/W	-

Factory default value: 1111 1111b

Bit	Name	Description
5	OCDPWM	PWM output state under OCD halt This bit decides the output state of PWM when OCD halts CPU. 1 = Tri-state pins those are used as PWM outputs. 0 = PWM continues.
4	OCDEN	OCD enable 1 = OCD Disabled. 0 = OCD Enabled. Note: If MCU run in OCD debug mode and OCDEN = 0, hard fault reset will disable. Only HardF flag be asserted.

29 IN-CIRCUIT-PROGRAMMING (ICP)

The Flash Memory can be programmed by “In-Circuit-Programming” (ICP). If the product is just under development or the end product needs firmware updating in the hand of an end customer, the hardware programming mode will make repeated programming difficult and inconvenient. ICP method makes it easy and possible without removing the microcontroller from the system. ICP mode also allows customers to manufacture circuit boards with un-programmed devices. Programming can be done after the assembly process allowing the device to be programmed with the most recent firmware or a customized firmware.

There are three signal pins, \overline{RST} , ICPDA, and ICPCK, involved in ICP function. \overline{RST} is used to enter or exit ICP mode. ICPDA is the data input and output pin. ICPCK is the clock input pin, which synchronizes the data shifted in to or out from MCU under programming. User should leave these three pins plus VDD and GND pins on the circuit board to make ICP possible.

Nuvoton provides ICP tool for MS51, which enables user to easily perform ICP through Nuvoton ICP programmer. The ICP programmer developed by Nuvoton has been optimized according to the electric characteristics of MCU. It also satisfies the stability and efficiency during production progress. For more details, please visit Nuvoton 8-bit Microcontroller website: [Nuvoton 80C51 Microcontroller Technical Support](#).

30 INSTRUCTION SET

The MS51 executes all the instructions of the standard 80C51 family fully compatible with MCS-51. However, the timing of each instruction is different for it uses high performance 1T 8051 core. The architecture eliminates redundant bus states and implements parallel execution of fetching, decode, and execution phases. The MS51 uses one clock per machine-cycle. It leads to performance improvement of rate 8.1 (in terms of MIPS) with respect to traditional 12T 80C51 device working at the same clock frequency. However, the real speed improvement seen in any system will depend on the instruction mix.

All instructions are coded within an 8-bit field called an OPCODE. This single byte should be fetched from Program Memory. The OPCODE is decoded by the CPU. It determines what action the CPU will take and whether more operation data is needed from memory. If no other data is needed, then only one byte was required. Thus the instruction is called a one byte instruction. In some cases, more data is needed, which is two or three byte instructions.

Table 28.2-1 lists all instructions for details. The note of the instruction set and addressing modes are shown below.

Rn (N = 0~7)	Register R0 To R7 Of The Currently Selected Register Bank.
Direct	8-bit internal data location's address. It could be an internal data RAM location (00H to 7FH) or an SFR (80H to FFH).
@RI (I = 0, 1)	8-bit internal data RAM location (00H to FFH) addressed indirectly through register R0 or R1.
#data	8-bit constant included in the instruction.
#data16	16-bit constant included in the instruction.
Addr16	16-bit destination address. Used by LCALL and LJMP. A branch can be any-where within the Program Memory address space.
Addr11	11-bit destination address. Used by ACALL and AJMP. The branch will be within the same 2K-Byte page of Program Memory as the first byte of the following instruction.
Rel	Signed (2's complement) 8-bit offset Byte. Used by SJMP and all conditional branches. The range is -128 to +127 bytes relative to first byte of the following instruction.
Bit	Direct addressed bit in internal data RAM or SFR.

[1] The MS51 does not have external memory bus. MOVX instructions are used to access internal XRAM.

[2] The most three significant bits in the 11-bit address [A10:A8] decide the ACALL hex code. The code will be [A10,A9,A8,1,0,0,0,1].

[3] The most three significant bits in the 11-bit address [A10:A8] decide the AJMP hex code. The code will be [A10,A9,A8,0,0,0,0,1].

31 ON-CHIP-DEBUGGER (OCD)

31.1 Functional Description

The MS51 is embedded in an on-chip-debugger (OCD) providing developers with a low cost method for debugging user code, which is available on each package. The OCD gives debug capability of complete program flow control with eight hardware address breakpoints, single step, free running, and non-intrusive commands for memory access. The OCD system does not occupy any locations in the memory map and does not share any on-chip peripherals.

When the OCDEN (CONFIG0.4) is programmed as 0 and LOCK (CONFIG0.1) remains un-programmed as 1, the OCD is activated. The OCD cannot operate if chip is locked. The OCD system uses a two-wire serial interface, OCDDA and OCDCK, to establish communication between the target device and the controlling debugger host. OCDDA is an input/output pin for debug data transfer and OCDCK is an input pin for synchronization with OCDDA data. The P2.0/ $\overline{\text{RST}}$ pin is also necessary for OCD mode entry and exit. The MS51 supports OCD with Flash Memory control path by ICP writer mode, which shares the same three pins of OCD interface.

The MS51 uses OCDDA, OCDCK, and P2.0/ $\overline{\text{RST}}$ pins to interface with the OCD system. When designing a system where OCD will be used, the following restrictions must be considered for correct operation:

1. If P2.0/ $\overline{\text{RST}}$ is configured as external reset pin, it cannot be connected directly to V_{DD} and any external capacitors connected must be removed.
2. If P2.0/ $\overline{\text{RST}}$ is configured as input pin P2.0, any external input source must be isolated.
3. All external reset sources must be disconnected.
4. Any external component connected on OCDDA and OCDCK must be isolated.

31.2 Limitation of OCD

The MS51 is a fully-featured microcontroller that multiplexes several functions on its limited I/O pins. Some device functionality must be sacrificed to provide resources for OCD system. The OCD has the following limitations:

1. The P2.0/ $\overline{\text{RST}}$ pin needs to be used for OCD mode selection. Therefore, neither P2.0 input nor an external reset source can be emulated.
2. The OCDDA pin is physically located on the same pin P1.6. Therefore, neither its I/O function nor shared multi-functions can be emulated.

3. The OCDCK pin is physically located on the same pin as P0.2. Therefore, neither its I/O function nor shared multi-functions can be emulated.

4. When the system is in Idle or Power-down mode, it is invalid to perform any accesses because parts of the device may not be clocked. A read access could return garbage or a write access might not succeed.

5. HIRC cannot be turned off because OCD uses this clock to monitor its internal status. The instruction that turns off HIRC affects nothing if executing under debug mode. When CPU enters its Power-down mode under debug mode, HIRC keeps turning on.

The MS51 OCD system has another limitation that non-intrusive commands cannot be executed at any time while the user's program is running. Non-intrusive commands allow a user to read or write MCU memory locations or access status and control registers with the debug controller. A reading or writing memory or control register space is allowed only when MCU is under halt condition after a matching of the hardware address breakpoint or a single step running.

CONFIG0

7	6	5	4	3	2	1	0
CBS	-	OCDPWM	OCDEN	-	RPD	LOCK	-
R/W	-	R/W	R/W	-	R/W	R/W	-

Factory default value: 1111 1111b

Bit	Name	Description
5	OCDPWM	PWM output state under OCD halt This bit decides the output state of PWM when OCD halts CPU. 1 = Tri-state pins those are used as PWM outputs. 0 = PWM continues. Note that this bit is valid only when the corresponding PIO bit of PWM channel is set as 1.
4	OCDEN	OCD enable 1 = OCD Disabled. 0 = OCD Enabled. Note: If MCU run in OCD debug mode and OCDEN = 0, hard fault reset will be disabled and only HardF flag be asserted.

32 CONFIG BYTES

The MS51 has several hardware configuration bytes, called CONFIG, those are used to configure the hardware options such as the security bits, system clock source, and so on. These hardware options can be re-configured through the parallel Writer, In-Circuit-Programming (ICP), or In-Application-Programming (IAP). Several functions, which are defined by certain CONFIG bits are also available to be re-configured by SFR. Therefore, there is a need to load such CONFIG bits into respective SFR bits. Such loading will occur after resets. These SFR bits can be continuously controlled via user's software.

Note: CONFIG bits marked as “-” should always keep un-programmed.

32.1 CONFIG0

7	6	5	4	3	2	1	0
CBS	-	OCDPWM	OCDEN	-	RPD	LOCK	-
R/W	-	R/W	R/W	-	R/W	R/W	-

Factory default value: 1111 1111b

Bit	Name	Description
7	CBS	CONFIG boot select This bit defines from which block that MCU re-boots after resets except software reset. 1 = MCU will re-boot from APROM after resets except software reset. 0 = MCU will re-boot from LDROM after resets except software reset.
5	OCDPWM	PWM output state under OCD halt This bit decides the output state of PWM when OCD halts CPU. 1 = Tri-state pins those are used as PWM outputs. 0 = PWM continues. Note that this bit is valid only when the corresponding PIO bit of PWM channel is set as 1.
4	OCDEN	OCD enable 1 = OCD Disabled. 0 = OCD Enabled. Note: If MCU run in OCD debug mode and OCDEN = 0, hard fault reset will be disabled and only Hard F flag be asserted.
2	RPD	Reset pin disable 1 = The reset function of P2.0/Nrst pin Enabled. P2.0/Nrst functions as the external reset pin. 0 = The reset function of P2.0/Nrst pin Disabled. P2.0/Nrst functions as an input-only pin P2.0.

Bit	Name	Description
1	LOCK	<p>Chip lock enable</p> <p>1 = Chip is unlocked. Flash Memory is not locked. Their contents can be read out through a parallel Writer/ICP programmer.</p> <p>0 = Chip is locked. Whole Flash Memory is locked. Their contents read through a parallel Writer or ICP programmer will be all blank (FFH). Programming to Flash Memory is invalid.</p> <p>Note that CONFIG bytes are always unlocked and can be read. Hence, once the chip is locked, the CONFIG bytes cannot be erased or programmed individually. The only way to disable chip lock is execute "whole chip erase". However, all data within the Flash Memory and CONFIG bits will be erased when this procedure is executed.</p> <p>If the chip is locked, it does not alter the IAP function.</p>

32.2 CONFIG1

7	6	5	4	3	2	1	0
-	-	-	-	-	LDSIZE[2:0]		
-	-	-	-	-	R/W		

Factory default value: 1111 1111b

Bit	Name	Description
2:0	LDSIZE[2:0]	<p>LDROM size select</p> <p>111 = No LDROM. APROM is 16 Kbytes.</p> <p>110 = LDROM is 1 Kbytes. APROM is 15 Kbytes.</p> <p>101 = LDROM is 2 Kbytes. APROM is 14 Kbytes.</p> <p>100 = LDROM is 3 Kbytes. APROM is 13 Kbytes.</p> <p>0xx = LDROM is 4 Kbytes. APROM is 12 Kbytes.</p>

32.3 CONFIG2

7	6	5	4	3	2	1	0
CBODEN	CBOV[2:0]			BOIAP	CBORST	-	-
R/W	R/W			R/W	R/W	-	-

Factory default value: 1111 1111b

Bit	Name	Description
7	CBODEN	CONFIG brown-out detect enable 1 = Brown-out detection circuit on. 0 = Brown-out detection circuit off.
5:4	CBOV[1:0]	CONFIG brown-out voltage select 11 = V_{BOD} is 2.2V. 10 = V_{BOD} is 2.7V. 01 = V_{BOD} is 3.7V. 00 = V_{BOD} is 4.4V.
3	BOIAP	Brown-out inhibiting IAP This bit decides whether IAP erasing or programming is inhibited by brown-out status. This bit is valid only when brown-out detection is enabled. 1 = IAP erasing or programming is inhibited if V_{DD} is lower than V_{BOD} . 0 = IAP erasing or programming is allowed under any workable V_{DD} .
2	CBORST	CONFIG brown-out reset enable This bit decides whether a brown-out reset is caused by a power drop below V_{BOD} . 1 = Brown-out reset Enabled. 0 = Brown-out reset Disabled.

34 REVISION HISTORY

Date	Revision	Description
2019.01.22	1.00	Initial version.

Important Notice

Nuvoton Products are neither intended nor warranted for usage in systems or equipment, any malfunction or failure of which may cause loss of human life, bodily injury or severe property damage. Such applications are deemed, "Insecure Usage".

Insecure usage includes, but is not limited to: equipment for surgical implementation, atomic energy control instruments, airplane or spaceship instruments, the control or operation of dynamic, brake or safety systems designed for vehicular use, traffic signal instruments, all types of safety devices, and other applications intended to support or sustain life.

All Insecure Usage shall be made at customer's risk, and in the event that third parties lay claims to Nuvoton as a result of customer's Insecure Usage, customer shall indemnify the damages and liabilities thus incurred by Nuvoton.

Please note that all data and specifications are subject to change without notice.
All the trademarks of products and companies mentioned in this datasheet belong to their respective owners.
